within ten years (1821-'30) produced over 100 plays, many of which are still considered masterpieces of their kind, such as *Le mariage enfantin*, *La loge du portier*, *La reine de seize ans*, *La marraine*, and *Le mariage de raison*. In many of his plays he was assisted by several other dramatists, the chief of whom were Germain Delavigne, Mélesville, Dupin, Varner, Carmouche, and Bayard. In 1822 he brought out at the Théâtre Français the drama of *Valérie*, the success of which was mainly due to the acting of Mlle. Mars. He also produced there, among other plays, *Une passion secrète* (1834); *Le verre d'eau* (1842); *Adrienne Lecouvreur* (with Legouvé, 1849); *La bataille de dames* (1851); *Mon étoile* (1853); and *Les doigts de fée* (with Legouvé, 1858). He wrote the libretti of *La dame blanche* for Boieldieu; *La neige*, *Fra Diavolo*, *Le domino noir*, *La sirène*, *Haydée*, *La Circassienne*, *La fiancée du roi de Garbe* (produced in 1864), and other operas, for Auber; *La fée aux roses* and *Le Juif errant*, for Halévy; *Les vèpres siciliennes*, for Verdi; *Les martyrs* and *Don Sébastien*, for Donizetti; and *Robert le Diable*, *Les Huguenots*, *Le prophète*, *L'étoile du Nord*, and *L'Africaine* (posthumously produced in 1865), for Meyerbeer; besides writing a great number of libretti for Massé, Adam, Clapisson, Boisselot, Balfe, Thomas, Offenbach, and other composers. He also wrote several novels, as *Carlo Broschi*, *Une maîtresse anonyme*, and *Piquillo Alliaga*. In 1836 he was elected to the French academy. At an early stage of his career he had secured a competence by his literary labors; his wealth increased afterward at a rapid rate, and he left a large fortune. As early as 1836 a catalogue of his works filled 36 columns of *La France littéraire*; now the whole number of his plays alone is estimated at more than 350. These have been printed separately, and in various dramatic collections. The first complete edition of Scribe's works is now in course of publication in Paris (vols. xi. and xii., 1875), to be comprised in 50 volumes.

SCRIBES (Heb. *sopherim*), a learned order among the ancient Hebrews. It was their duty to keep the official records of the kingdom, to make transcripts of the law, and to expound and teach it. In the time of David the name of a scribe is mentioned among the high officers; and under his successors they constituted a much esteemed and highly influential body, recognized and supported by the state. In the later times of the nation they recorded and expounded the oral traditions. In the New Testament they appear as a body of high officers, members of the sanhedrim.

SCRIPTURES, Holy. See BIBLE.

SCRIVEN, an E. county of Georgia, bordering on South Carolina, bounded E. by the Savannah river, and S. W. by the Ogeechee; area, 540 sq. m.; pop. in 1870, 9,175, of whom 4,888 were colored. The surface is level and the soil sandy. Pine timber is exported largely. It

is traversed by the Central railroad of Georgia. The chief productions in 1870 were 153,242 bushels of Indian corn, 10,962 of peas and beans, 30,789 of sweet potatoes, 3,086 bales of cotton, and 12,552 gallons of molasses. There were 609 horses, 565 mules and asses, 3,067 milch cows, 6,049 other cattle, 3,225 sheep, and 9,416 swine. Capital, *Sylvania*.

SCRIVENER, Frederick Henry, an English clergyman, born at Bermondsey, Surrey, Sept. 29, 1813. He graduated at Trinity college, Cambridge, in 1835, was appointed assistant master of the king's school, Sherborne, and in 1839 became curate of Sandford Orcas, Somerset. In 1846 he was appointed head master of Falmouth school, and since 1861 has been rector of Gerrans, Cornwall. In 1870 he was chosen one of the company of revisers of the authorized version of the New Testament. His publications include "A Supplement to the Authorized Version of the New Testament" (1845); "A Collation of about Twenty Manuscripts of the Greek Testament deposited in England" (1853); "Contributions to the Criticism of the New Testament, being the Introduction to the Codex Augiensis and Fifty other Manuscripts" (1859); *Novum Testamentum Græcum*, text of Stephens of 1550, with various readings of Beza, Tischendorf, Tregelles, &c. (1860; new ed., 1867); "Plain Introduction to the Criticism of the New Testament" (1861); "Full Collation of the Codex Sinaiticus with the Received Text of the New Testament, with Critical Introduction" (1863); and "Bezæ Codex Cantabrigiensis, 1581, edited with Prolegomena, Notes, and Facsimiles" (1864).

SCRIVENERS' PALSY, or *Writers' Cramp*, a deranged condition of the motor nerves distributed to the muscles of the fingers and thumb holding the pen. It often completely prevents writing, and, although not precisely paralysis, is equivalent to it. There appears to be a want of coördination of the muscular movements engaged in writing, and in this respect it has some connection with locomotor ataxy. The constant employment of the same movements creates an irritation, which is often attended by pain and excites uncontrollable movements in the thumb and index finger, causing motions which make the writing illegible. A persistent attempt to write only increases the irritation and confusion, and the irregular contractions extend from the muscles of the fingers to those of the forearm and even the upper arm. The disease often attacks musicians, sempstresses, milkmaids, shoemakers, and nail smiths, and therefore it has also been known under the names cobbler's spasm and milkers' spasm. It is more frequent among men than among women, and most common between the ages of 30 and 50. It chiefly attacks clerks, teachers, and professional penmen, and most frequently those who pay little regard to the mechanism of writing. Rest and a good diet, with tonics, particularly iron, form the most rational gen-

eral treatment. Niemeyer found benefit in the use of the galvanic current, which may be passed from above on the muscles of the fore arm, the tendons of which pass to the thumb and index finger. Strychnine has sometimes produced good results, and where the patient labors under malarious influence the use of quinine has been found beneficial.

SCROFULA, a blood disease manifesting itself in a great variety of organs, and characterized when fully developed by the presence of a peculiar unorganized matter termed scrofulous. The name is supposed to be derived from the Latin *scrofa*, a sow, that animal being regarded as especially liable to humors of a similar character. It was called *struma* by Celsus, Pliny, and other Latin writers, from *struere*, to heap up. The disease is transmitted from parent to child, though like other hereditary diseases it frequently passes over one generation to attack the next. It is closely allied to pulmonary consumption; consumptive parents have often a scrofulous or strumous progeny, and *vice versa*. A damp cold atmosphere is favorable to its development, while it is probable that overcrowding and want of ventilation, aided by unwholesome and insufficient food, may originate it *de novo*. When the predisposition to the disease exists, everything that tends to depress the vital forces exercises an unfavorable influence.—The scrofulous habit, when strongly marked, is easily recognized. If the skin be fair, the complexion is often peculiarly brilliant, but the color seems laid on in one large patch, leaving the surrounding skin of an unnatural whiteness; the wings of the nose are thick, the upper lip often swollen, and the lips become cracked and rough on exposure to cold. The skin is unusually delicate and irritable; the patient suffers very readily from chilblains, and in childhood is more liable than others to cutaneous diseases. The mucous membranes partake the delicacy and irritability of the skin. The edges of the eyelids are apt to be red and swollen; the eye is very liable to be attacked by a peculiar inflammation (see OPHTHALMIA); hæmorrhage from the nose, cold in the head, and enlarged tonsils are frequent. The muscles commonly want firmness, and the whole system is deficient in stamina. Sometimes the scrofulous diathesis is marked by a dark complexion, a rough, dry skin, and a pasty, unhealthy look; the movements are sluggish, the habit of body indolent, and the intellect dull. When scrofula is fairly developed, its essential element is the deposition of an unorganized, brittle material, generally of the consistency of new cheese. In the lungs the presence of this matter constitutes tubercular consumption; in the mesenteric glands, *tabes mesenterica*; in the arachnoid membrane of the brain, acute hydrocephalus; in the lymphatic glands, bones, &c., scrofula. Scrofula is eminently a disease of childhood, while consumption belongs to a later period; but neither is confined to any age. One of the forms in which scrofu-

la most commonly and earliest shows itself is swellings of the lymphatic glands in various parts of the body, more particularly about the neck. These become enlarged and firmer, and after a time a deposition of the peculiar curd-like matter is found to have taken place in their interior. After a time suppuration occurs, the swellings become softer, and the skin over them assumes a dusky red hue, gradually becomes thinner, and finally bursts, giving outlet to an unhealthy pus mixed with the curd-like deposit of the disease. The ulcers thus left heal slowly and with difficulty, and unless great care is exercised produce deformed cicatrices. Occasionally, but rarely, scrofulous glands undergo a process of cure without the occurrence of suppuration, the swelling gradually subsiding, and the tuberculous matter, by the absorption of its thinner part, being converted into a chalky concretion.—In the management of strumous infants much can be done to guard against the development of the disease. If the mother be affected, a healthy wet nurse if possible should be employed; the sleeping room of the child should be large and well ventilated; it should be bathed daily, at first in warm, and as it acquires strength in cold water, well dried, and thoroughly rubbed; it should be warmly clothed, and exposed as much as possible to the light and air. As it advances in age, the diet should be simple and digestible, but abundant and nutritious; the child should have reasonable but not excessive exercise, and should be in the open air as much as possible; while if it be, as is frequently the case, bright and precocious, great care should be taken not to stimulate its intellect too early and too much. When the disease shows itself, a residence by the seaside during summer is frequently of service. Remedial agents are to be sought in the preparations of iron and iodine, in quinine and the bitter tonics.

SCRUPLE (Lat. *scrupulum*, a little pebble), a weight equal to the third part of a dram or the 24th part of an ounce, as used by apothecaries. The *scrupulum* (also written *scripulum* and *scriptulum*) was $\frac{1}{24}$ of the Roman *uncia*, and afterward $\frac{1}{60}$ of an hour. The 60th part of this was *scrupulum secundum*, and the 60th of this *scrupulum tertium*, whence our terms seconds and thirds applied to these divisions.

SCUDDER, John, an American missionary, born in New Brunswick, N. J., Sept. 3, 1793, died at Wynberg, Cape of Good Hope, Jan. 13, 1855. He graduated at Princeton in 1813, studied medicine, and settled in New York. He subsequently offered himself to the American board as a missionary, studied theology, and in 1819 was ordained as a minister of the Reformed Dutch church on board the ship which carried him to India. For 19 years he labored in Ceylon, where he conducted a large hospital. In 1839 he was transferred to Madras. In 1842 he visited America, and after his return to India in 1846 resumed his labors, but in 1854 went for his health to the Cape of Good

Hope. He published "The Redeemer's Last Command," "The Harvest Perishing," "An Appeal to Mothers," "Knocking at the Door," "Passing over Jordan," "Letters to Children on Missionary Subjects," "Grandpapa and Little Mary," &c.—His eight sons and two daughters all became missionaries. One, the Rev. Henry Martyn Scudder, returned to America in 1864, and became pastor of a Presbyterian church in San Francisco in 1865, and of a Congregational church in Brooklyn in 1871.

SCUDÉRY, or **Sendérl**. **I. Georges de**, a French author, born in Havre about 1601, died in Paris, May 14, 1667. After serving without distinction in the army, he became known by attacks upon Corneille's *Cid*, and by his devotion to Richelieu, who had him admitted to the academy, and appointed governor of a small fortress near Marseilles; and in 1662 he received a pension of 600 livres. His factitious reputation was increased by his name being published as the author of his sister's most celebrated works, though they were mainly written by her alone. Boileau finally destroyed the ephemeral prestige of his plays and of his epic *Alaric*. **II. Madeleine de**, Mlle., a French authoress, sister of the preceding, born in Havre, June 15, 1607, died in Paris, June 2, 1701. She was called "another Sappho" and a "tenth muse," although her excessive mannerism injured the hôtel Rambouillet, where she was conspicuous, and Boileau satirized her exaggerated sentimentality. But her romances, *Ibrahim* (4 vols., 1641), *Artamène, ou le grand Cyrus* (10 vols., 1649-'53), and *Clélie* (10 vols., 1656; new ed., 1731), enjoyed great popularity on account of their delineations of contemporary characters, especially *Artamène*, which served as the basis of Cousin's *Société française du 17^e siècle* (1858). Among her other writings are *Almahide, ou l'Esclave reine* (8 vols., 1660); *Discours sur la gloire* (1671), which received the first rhetorical prize ever awarded by the academy; *Conversations sur divers sujets* (4 vols., 1680-'84); *Conversations de morale* (4 vols., 1686-'8); and letters which, though not collected, are among her brightest efforts. A selection from her writings appeared in 1766, and in many later editions, under the title of *Esprit de Mademoiselle de Scudéry*; and a memoir of her was published in Paris in 1873.

SCULPIN. See **BULLHEAD**.

SCULPTURE (Lat. *sculpere*, to cut out, to carve), literally, the art of cutting or carving any substance into images. The term is used generally to indicate any process by which the forms of objects are represented by solid substances, and therefore includes carving, modelling, casting, whether in metal or other materials, and gem engraving. Sculptured images consist either of insulated figures or parts of figures or groups, technically called the "round;" of figures attached to a background, from which they are more or less raised, and designated according to the degree of the "relief," as it is termed, *alto rilievo*, *basso ri-*

lievo, and *mezzo rilievo*; or of figures which, without projecting from the face of the original ground, have their outlines sunk into it, and are rounded on the principles of *basso rilievo*. This method of working occurs chiefly in Egyptian sculpture, and may be termed *relieved intaglio*. The materials employed by the sculptor include almost every substance capable of being carved, cast, or moulded. For carving, porphyry, basalt, granite, marbles of many varieties, alabaster, ivory, bone, and wood have been in use from a remote period, the three first named substances being those used by the Egyptians, while the Greeks and Romans worked chiefly in marble. Of the latter material, that most esteemed by the ancients was the pure white marble found in the island of Paros, and thence called Parian, next to which in quality was that procured from Mounts Pentelicus and Hymettus in the neighborhood of Athens. The finest Italian marble was the Carrara, which still maintains its old celebrity; but many Roman sculptors wrought from marbles procured in Africa. The finest marbles in modern use are from Italy. Alabaster sculpture is best illustrated by specimens exhumed at Nineveh. Wood was chiefly employed in the primitive stages of the art, and the kinds most in vogue were oak, cedar, cypress, sycamore, pine, box, fig, and ebony. Few works of this description are extant, notwithstanding Pliny and other ancient authors speak of the durability of ebony, cedar, and other species. Occasionally figures for special purposes, as funeral ceremonies, were made of aromatic gums, and even of hay. For modelling, clay, stucco, plaster, and wax were used in the infancy of the art; and images of baked clay, known as terra cotta work, were indefinitely multiplied by means of moulds of the same material, into which the soft clay was pressed. Terra cotta was used for an infinite variety of purposes besides statuary, the objects formed from it being generally small and painted, and of a hardness, produced by the action of fire, almost equalling that of stone. The metals employed in casting are gold, silver, iron, tin, copper, lead, and their compounds. Electrum, a substance formed of one part of gold to four parts of silver, was used as remotely as the Homeric age; but the composition called by the Greeks *χαλκός*, by the Romans *æs*, and by the moderns bronze, has in all ages been preferred for the purposes of sculpture to any other metal, and the greater part of the antique statues and sculptured ornaments now extant have been formed from it. From the varieties mentioned by ancient writers, it appears that many centuries before the Christian era a very considerable degree of skill had been acquired in its preparation; and the colossal proportions of many of the bronze works extant or on record point to a facility in the processes of casting not inferior to the art of modern times. Metal statues, however, were not always cast, but, in the earlier ages

at least, were made of small plates hammered into the desired shape, and fastened by nails or cramps, or of solid pieces beaten into shape. Sometimes, according to ancient authors, peculiar effects of color, such as a blush or pallor upon the cheeks, were given by Greek sculptors to works of this class by a fusion of different metals; but the descriptions by Plutarch and others do not afford a very satisfactory account of the process, and it seems more probable that the statues were colored after being cast, as Pliny says was the practice with the Egyptians. Coloring was not confined to bronzes, but among eastern nations, as well as with the Greeks, statues in marble and other materials were frequently heightened by color and a profusion of ornament, whence they were termed by the Greeks polychromic. When different kinds of marble or stone and of different colors were combined in the same work, it was called polythitic, to distinguish it from the simpler monolithic sculpture. Both methods are distinct from the so-called toreutic art of the ancients, which included the working of precious metals combined with other substances, as exemplified in Homer's description of the shield of Achilles. The Greek sculptors sometimes introduced foreign substances into marble statues, as precious stones or glass for eyes. A species of sculpture called chryselephantine, in which the flesh parts of the figure were of ivory and the draperies of gold, was also employed by the Greeks for statues of tutelar divinities intended to testify to the wealth, liberality, or piety of a state or individual. The statue of the Olympian Zeus by Phidias affords the most illustrious example of this.—Sculpture was probably the earliest developed of the imitative arts. So far as experience has shown, it had no special birthplace, but sprung up naturally in all parts of the world, taking its origin everywhere in the imitative faculty of man, although the practice of it in certain countries was undoubtedly influenced by the higher civilization of others. The first efforts in sculpture were probably monumental. A block of stone rudely fashioned into some simple form, or even a pile of stones, originally sufficed for a memorial; and repeated instances occur in the Mosaic history of the erection of monuments of this kind. The next step may be traced to the desire in a primitive state of society for some visible, tangible object representing the deity commonly worshipped. But as the deities worshipped by the earliest races were heavenly bodies or abstract qualities, such representations could only be symbolical; hence in all probability the first statues of gods were simple pillars of stone having no resemblance to the human figure, and indicating their purpose only by certain marks or hieroglyphics carved upon them; and the first statues fulfilling in any considerable degree the conditions of art were of men distinguished as heroes, benefactors, or founders of nations. When in process of time such indi-

viduals became invested with divine attributes, the visible representation of their forms as objects of worship became necessary, and sculpture first assumed its legitimate functions. The art, thus early associated with religious worship, was naturally considered inapplicable to ordinary purposes, and in many instances was wholly controlled by hierarchical influence. The supernatural character assigned by grossly superstitious races to the forms of these newly created deities, as exemplified in the monstrous creations of the Chinese, Hindoo, and Egyptian mythology, was gradually embodied in certain fixed types from which no deviation was permitted; and this circumstance, together with the limited field of practice, caused sculpture in many parts of the world to remain almost from its birth a mere mechanical art.—The first artists on record as sculptors are Bezaleel and Aholiab (about 1500 B. C.), who made the ornaments of the tabernacle (Exod. xxxi.), although long previous to their time the art of working in metal, stone, and wood was known to various eastern nations. Abundant passages in the Old Testament show that the Hebrews practised it with success, as did also the Phœnicians; but no specimens of the sculpture of either nation remain. Of Assyrian sculpture nothing was known from actual observation previous to the excavations of Botta, Layard, and their successors, by which the arts of a race whose history is lost in the mythical ages have been suddenly and minutely brought to light. The specimens exhumed are for the most part bass reliefs on alabaster slabs, the subjects delineated being colossal human-headed bulls and other grotesque personages from the Assyrian mythology, battles, hunting scenes, processions, ceremonials, &c., executed according to a code of conventional rules. (See NINEVEH.) Although none of them can be assigned a high rank as works of art, the spectator cannot but be struck by the majesty and even the severe grandeur of some of the larger figures, and by the skill with which the characteristics of individual animals and the details of elaborate compositions are represented. The Assyrians also excelled in bronze castings. Of the wonders of Babylon and the perfection to which the Chaldeans carried the art of casting in bronze and the precious metals, we know nothing beyond the accounts of Herodotus and other ancient writers. Among the Persians sculpture was never employed for religious purposes, and the art as practised by them was evidently derived from the Assyrians. Worshipping no deity which could be represented by any form, they regarded images of gods as marks of barbarism and impiety; and wherever they appeared as conquerors such works, with the temples enclosing them, were invariably destroyed. But their art, notwithstanding it was unrestrained by hierarchical influences, was never marked by taste or in any sense progressive. The sculptures of Persepolis represent principally processions

and combats, the figures in which are heavily draped and exhibit little variety, action, or character. The sculpture of the remoter eastern nations, including the Chinese and Hindoos, has little to recommend it in the qualities of art, and affords no assistance in tracing the history of our subject. The hierarchical authority, by confining its exercise to mythological subjects, prevented it from becoming imitative or progressive. In vastness of scale and the sentiment of repose the Hindoo sculptures at Ellora, Elephanta, and elsewhere, are equal to the productions of any Asiatic race.—The Egyptians, perhaps more than any other nation of antiquity, associated the practice of sculpture with religious worship; hence most of their extant works of this class comprise conventional representations of deities and their attributes or qualities. Recent discoveries, however, show that their earliest sculptures were free from restraint, and represented animate and inanimate forms with great accuracy; whence the remark of Lenormant: "Alone of all the world the Egyptians began with living reality to finish with hieratic convention." A striking example of their early proficiency is afforded in a wooden statue of one Ra-em-ke, preserved in the museum at Boolak near Cairo, and attributed to the era of the fifth dynasty, or nearly 4000 B. C. (according to Mariette). The body is admirably modelled, and the head life-like. This primitive art period expired with the sixth dynasty, and from the eleventh dynasty, or formation of the middle empire, about 3000 B. C., Egyptian artists formed a sort of hereditary craft, whose labors, controlled by a rigid code of rules prescribed by the sacerdotal authority, exhibit a uniformity of results so striking as to justify the statement that until the conquest of the country by the Macedonian Greeks, 332 B. C., a period of nearly 2,800 years, there was but one epoch in Egyptian sculpture. A Græco-Egyptian style succeeded with the Ptolemies, and expired with the art itself. Not only were the artists forbidden to make innovations, but they were never allowed, Plato tells us, "to invent any new subjects or any new habits. Hence the art remains the same, the rules of it the same." The standard types of form were archaic in character and deficient in action and expression, which will account for the utter absence of anything approaching grace, symmetry, or elegance in Egyptian art. The figures are generally equally poised on both legs, one of which is sometimes slightly advanced; the arms either hang down straight on each side, or if one be raised, it is at a right angle across the body; and the head looks directly in front. Many statues, however, are seated or kneeling, the former attitude being that in which, on the whole, Egyptian sculptors excelled; and the colossal sitting figures of their kings frequently exhibit grandeur of proportion and repose and dignity of expression. Anatomy was little regarded in

representations of the human form, and the draperies were of the simplest character, frequently falling straight to the ground, without folds. Where elaborate representations in bass relief or intaglio of battles, processions, or religious ceremonies were attempted, greater freedom seems to have been allowed the artist; and in this class of works, as well as in occasional heads, such as the so-called Young Memnon in the British museum, there are evidences of inventive power and a feeling for ideal beauty, which, but for the restraints imposed upon the sculptor, might have borne worthy fruits. Egyptian sculpture of all kinds was usually colored, and statues of the hardest granite, the material most commonly employed, are as cleanly cut as marble and beautifully polished.—Etruscan sculpture, so far as can be ascertained by existing specimens, was connected in a greater or less degree with that of the Greeks, although there is reason to believe that previous to the arrival of Greek colonists in Etruria a purely national style was in existence there. K. O. Müller has observed that the art of the country, being receptive rather than creative, and not indigenous, began to decline as soon as deprived of the Greek influence. The best specimens of Etruscan sculpture in existence are bronze works of the kind known as *Tuscanica signa*, which were highly esteemed by Roman connoisseurs. They are characterized by a stiff, archaic style resembling the early Greek, which seems to have been retained as the standard. Well known examples of Etruscan bronzes are the "She Wolf" of the capitol at Rome, and the "Chimæra" at Florence. Innumerable smaller figures have been found, and such was the facility of the people in casting, that after the capture of Volsinii by the Romans, about 280 B. C., 2,000 statues in bronze were carried away by the victors. Etruscan carvings, whether in wood or stone, are unskilful, but their terra cotta vases and ornamental work are of high artistic value. The Etruscan vases, however, so celebrated for their elegance of form and the paintings with which they are embellished, are now believed to be of Greek origin.—In the hands of the Greeks sculpture was brought to a degree of perfection scarcely approached in modern times, and quite as marked, in comparison with the progress of other ancient nations, as their superiority in every department of imitative art and literature. Similar causes contributed to this universal excellence, the principal of which, according to Winckelmann, were the innate genius of the people, their religion, and their social and political institutions. While in the East, and even among the Etruscans, art never advanced beyond the types established almost at its birth, the Greeks, led on by an intuitive sense of beauty, which was with them almost a religious principle, aimed at an ideal perfection, and, by making nature in her most perfect forms their model, "ac-

quired a facility and a power of representing every class of form unattained by any other people, and which have rendered the terms Greek and perfection, with reference to art, almost synonymous." In respect to climate, physical beauty, mechanical ingenuity, or manual dexterity, the Greeks had little if any advantage over contemporary races; and yet, whatever was the purpose to which sculpture was applied, their superiority was indisputable. Like the works of the painters who effected the revival of art in modern times, the sculptures of the best period in Greek history were almost exclusively public, and intended for the moral or religious improvement of the people, or as an incentive to noble deeds. When the sculptor ceased to be influenced by these motives, his art began to decline, as Italian art under similar conditions languished after the brilliant period of Raphael and Michel Angelo. Greek sculpture may be divided into a semi-mythic or archaic period, a period of grandeur and power, a period of refinement or physical beauty, and a period of decline. The remains of the first period are not unlike the earlier attempts of other nations, although at its close, notwithstanding the hierarchical influence, a steady progress toward excellence is discernible. The first sculptors on record are purely mythical, and may be regarded as personifications of particular branches of art, or the representatives of families of artists, rather than actual personages. Such was Dædalus, whose name indicates merely an artist in general, and of whom it has been observed that "the stories respecting him are more like allegorical accounts of the progress of the arts than anything else." For many ages sculptors claimed an actual descent from Dædalus, whence they were called Dædalids; and their works, known as *δαίδαλα*, represent the first attempts to replace the blocks of wood and stone which originally symbolized the images of deities, by statues having some resemblance to life or nature. These were generally of wood, ornamented with gilding, colors, and real drapery, although long before the commencement of authentic history other materials began to be used. Phidon of Argos, who is said to have struck the first money in Greece (748 B. C.), probably introduced the employment of metals in statuary; and the most ancient Greek statue in this material mentioned by classical authors was one in bronze of Zeus, by Learchus of Rhegium, who is supposed to have flourished as early as 700 B. C. This, however, was constructed of thin plates bent into the required shape, and riveted together. Glaucus of Chios or Samos (690) was the reputed inventor of the art of soldering metals; and to Rhœus of Samos, and his son Theodorus, was ascribed the invention of modelling and casting metals, besides other improvements in the art (about 600). Pliny is of opinion that the first marble statues date from the commencement of the Olympiads, although Dipœnus and

Scyllus of Crete, who flourished in the early part of the 6th century B. C., are the first artists who were celebrated for their works in marble. Sculptured figures on architectural monuments were executed as early as the Homeric epoch, such as the two lions in relief on the ancient gate of Mycenæ, which, with other archaic remains of Greek statuary and metal work, reflect, it is asserted, the influence of Assyrian civilization. The period between the age of Homer and the 50th Olympiad (580), comprising about three centuries, witnessed the discovery of the chief processes essential to the practice of sculpture; but, from the restraints imposed by religion, the art made little progress even among the Asiatic Greeks, by whom it was most successfully cultivated. Statues of gods after fixed types were almost the only ones made. Toward the middle of the 6th century those changes took place by which the early archaic style was gradually merged in that of the second epoch. The athletic contests at the public games familiarized the artists with the beautiful forms of the human body, and the practice of erecting statues of the victors in these contests, which began about 550, gave a surprising impulse to the art. The subject, not being religious, admitted of a greater play of inventive powers, and the improvement thus produced in the statues of men was extended to those of gods, which gradually began to assume grace and grandeur. The hereditary cultivation of sculpture, under the influence of which conventional types were carefully transmitted to successive generations, also ceased about this time, and individual artists were left free to follow the dictates of their own genius. These circumstances, with the disastrous consequences to Asiatic art of the Ionian revolt against Darius Hystaspis, and the patriotic spirit evoked by the Persian invasion, gave increasing vigor to sculpture in Greece proper, where the hardness and stiffness of the first period are lost in the grandeur and ideal beauty of Phidias and his contemporaries, who united "the principles and the stability of the Dorian genius with the liberty and grace of the Ionian." Many works in marble and bronze belonging to the latter or transition portion of the archaic period are still extant, the most characteristic being the Selinuntine and Æginetan marbles, now deposited in Palermo and Munich, which formed part of the decorations of temples. Sicyon, Ægina, and Argos had hitherto been the chief schools of the art; but during the period upon which we are now entering, from 480 to about 400 B. C., Athens was its most distinguished seat, her supremacy being disputed only by Argos. The Athenian and Argive sculptors, animated by the intellectual activity which the Persian invasion developed, and which manifested itself not merely in the cultivation of literature and the fine arts, but in all the social and political relations of the Hellenic races, vied with each other in disseminating over

Greece and her colonies a series of works which became the models of form for their countrymen as well as for all succeeding sculptors. Statuary was at this time almost exclusively public, and the chief sculptors, Hegias, Pythagoras of Rhegium, Calamis, Ageladas, Phidias, Agoracritus and Alcamenes, both pupils of Phidias, Myron, and Polyclethus, are known mainly by their statues of gods and heroes and their historical groups for the temples, porticoes, theatres, and gymnasia, built from the spoils of war or the profits of newly developing commerce. Of these Phidias, Myron, and Polyclethus, all scholars of Ageladas of Argos, were the most famous, and their works exhibited the dignity and almost passionless tranquillity of mind characteristic of a heroic age, and of the lofty purposes for which its artists labored. Phidias of Athens, whose name is associated with the noblest architectural monuments and sculptures of the splendid era of Pericles, is generally placed at the head of all the sculptors of antiquity in the qualities of sublimity and severe beauty, his works bearing the same relation to those of subsequent stages of the art that the dramas of Æschylus do to the more polished productions of Sophocles or Euripides. His chryselephantine statues of Athena and the Olympian Zeus, the most celebrated of the kind ever made, exist only in the descriptions of ancient authors; but in the Elgin marbles, executed under his direction and in part perhaps by himself, as has been generally supposed, we fortunately have splendid and characteristic specimens of his genius. (See ELGIN MARBLES, and PHIDIAS.) The Phigalian marbles in the British museum and the casts of the sculptured fragments from the temple of Theseus, in the same institution, are also in the style of Phidias or his school. Myron, who worked chiefly in bronze, was a great master of expression, and, from the frequent and honorable mention of him by classical authors, must have been one of the most esteemed sculptors of antiquity. He was celebrated for his figures of animals, but the *discobolus* or quoit player, of which the palazzo Massimi in Rome and the British museum possess copies, is the only work by which he is now known. Polyclethus, the head of the Argive school, as Phidias was of that of Athens, rivalled his great contemporary in every department of his art, except the representations of gods, in which Phidias was never equalled. He even gained a victory over him in the representation of an Amazon. His statues of athletes were considered the perfection of manly beauty, and a youthful *doryphorus* (spear bearer) was so accurately proportioned as to be a standing model for sculptors. Toward the close of the Peloponnesian war a change took place in the habits and feelings of the Athenian people, under the influence of which a new school of statuary was developed. The people, spoiled by luxury and craving the pleasures and excitements which the prosperity of the

age of Pericles had opened to them, regarded the severe forms of the older masters with even less patience than the austere virtues of the generation which had driven the Persians out of Greece. The sculptors, giving a reflex of the time in their productions, instead of the grand and sublime, cultivated the soft, the graceful, and the flowing, and aimed at an expression of stronger passion and more dramatic action. Jupiter, Juno, and Minerva, the favorite subjects of the Phidian era, gave place to such deities as Venus, Bacchus, and Amor; and with the departure of the older gods departed also the serene and composed majesty which had marked the representations of them. The great sculptors of this period of refinement or sensuous beauty, which begins about 400, were Scopas, Praxiteles, and Lysippus, by whom the art was brought to almost absolute perfection in respect to gracefulness of form and expression and technical qualities. Scopas excelled in single figures and groups, combining strength of expression with grace, rather than in architectural sculpture. The celebrated group of Niobe and her children in the museum at Florence is attributed to him. The *Venus Victria* of the Louvre, called also the Venus of Milo, was formerly also considered his work, but may more reasonably be regarded as a remnant of the sublime style developed under Phidias. The slab from the mausoleum of Halicarnassus, representing the battle of the Amazons, now in the British museum, is undoubtedly from his hand. Praxiteles was almost unrivalled as a sculptor of the female figure, and his statue of the Cnidian Aphrodite, modelled from the courtesan Phryne, was a masterpiece of sensual charms. This work is said to have been the first instance in which any artist had ventured to represent the goddess entirely divested of drapery, and the new ideal thus formed was frequently imitated by succeeding sculptors. It is doubtful whether any copies of it are in existence, although the Venus of the Vatican and that of the museo Pio Clementino are supposed to be such. The works of these two artists were executed chiefly in Parian marble, a material which now came into general use for single figures or groups, while the costly chryselephantine statues, and those made of wood and stone, called acroliths, gradually disappear. While Scopas and Praxiteles represented what is known as the later Attic school, Lysippus of Sicyon carried out the principles of the Argive school of Polyclethus by representing the human form and athletic power in the highest perfection. He paid great attention to details, and by a careful imitation of nature gave a realistic character to his productions, under the influence of which portrait statues began to take the place of ideal creations. He appears to have worked only in bronze, and was the favorite sculptor of Alexander the Great, whose statues he had the exclusive privilege of making. The commencement of the fourth and last period in

Greek sculpture, about 320 B. C., found the schools of Praxiteles and Lysippus in considerable vigor, although the artists contented themselves with imitating their predecessors rather than opening any original path of design. Sculpture consequently began to decline, its decay being hastened by the disturbances which followed the dismemberment of Alexander's vast empire. Until the middle of the 3d century B. C., however, there appears to have been no lack of reputable artists, and new schools sprang up in Rhodes, Alexandria, Pergamus, Ephesus, and elsewhere in the East, the followers of which too frequently lent their talents to the execution of grossly flattering portraits of kings, and other unworthy purposes. The school of Rhodes could boast of Chares, the sculptor of the famous Colossus. To this period are generally attributed by art critics Agesander's group of Laocoön and his sons, which, together with the Farnese bull at Naples, emanated, according to Pliny, from the Rhodian school; the Apollo Belvedere in the Vatican, the "Hermaphrodite" at Paris, the torso of the Belvedere at Rome, the Farnese Hercules, and the "Dying Gladiator." Bronze and marble were the materials principally in vogue, and the former was gradually superseded by the latter. Shortly before the capture of Corinth by the Roman general Mummius, 146 B. C., a transient revival took place in Athens, during which the statue known as the Venus de' Medici was produced by Cleomenes, although according to some authorities it is possibly the work of Alcamenes, the pupil of Phidias; but the reduction of Greece to the condition of a Roman province gave the death blow to the art, which degenerated into a mere handicraft. The ancient seats of civilization, stripped by the conquerors of their choicest art treasures, no longer afforded to the sculptor the models consecrated by time and national pride; and the Greeks, having neither the means nor the high inducements to practise their art at home possessed by preceding generations, transferred their labors in the 1st century B. C. to Italy. —As early as the consulship of P. Cornelius Scipio Nasica, 162 B. C., the city of Rome possessed numerous statues of gods and public men, executed probably by Greek and Etruscan sculptors, the latter of whom had long previously made the Romans familiar with their peculiar artistic creations. The overthrow of Greece and her colonies, however, gave the first impulse to the cultivation of sculpture in Rome; and after the wholesale plundering of Greek cities by Sulla in 86 B. C., a taste for art and for collecting choice specimens of sculpture and painting began to be developed among the wealthy Romans. Toward the close of the republic Rome was full of Greek sculptors, some of whom, without having originality of conception, were not unworthy descendants of the great schools of their native country. A creditable specimen

of their skill is afforded in the so-called statue of Germanicus in the Louvre. Julius Caesar was an intelligent collector of statuary, and during the reign of Augustus the art was liberally encouraged by the emperor and other powerful patrons. Caligula and Nero ransacked Greece for sculptures, and the former introduced the barbarous custom of decapitating the statues of gods and illustrious men for the purpose of substituting his own likeness, in which he was imitated by many of his successors. Down to the time of Trajan, the principal sculptured works consisted of reliefs on public monuments, such as those adorning the arches of Titus and Trajan, and statues and busts of the emperors, many of which are meritorious in point of execution, and display considerable fancy and invention in the treatment. The vigorous character of Trajan gave new life to the arts in Greece and Rome, and his reign and those of his successors Hadrian and Antoninus Pius have been called the golden age of Italian sculpture. Hadrian was one of the most accomplished connoisseurs of the time, as was evinced by the modern excavations at his villa near Tivoli, and by his influence induced contemporary sculptors to exchange the representations of common subjects, to which they had gradually begun to confine themselves, for those more characteristic of earlier artists. The pure Greek style was revived with considerable success, and contemporary with it flourished another, half Greek and half Egyptian, suggested by the recent introduction of the worship of Egyptian deities into Italy. The portrait statues of this period are particularly fine, and the ideal creations, of which the statues and busts of the emperor's favorite Antinous may be regarded as specimens, have been placed on an equality with the works of the most finished Greek period. The efforts of Herodes Atticus, one of the most liberal and enlightened patrons of art on record, also did much to prolong this revival; but after the middle of the 2d century of our era the art exhibited an uninterrupted decline. The sculptures on the arch of Septimius Severus (A. D. 203) are far inferior to the productions of Hadrian's time; and those on the arch of Constantine, erected a century later, show that originality of design and executive ability were then nearly extinct. The dismemberment of the empire completed the destruction of the arts in Italy, and during the troubled ages which succeeded, the finest efforts of the old sculptors fell a prey to barbarian or iconoclastic fury, or were destroyed in conflagrations. Constantinople, in which a vast number of bronzes, marbles, and pictures had been collected by the eastern emperors, continued for several centuries to be almost the only repository of such objects; but the capture of the city by the Latins in 1204 having involved these in destruction, the knowledge of antique art for a time passed away from the world.—Roman

sculpture may be described in general terms as a continuation of that of Greece; the best artists were Greeks, and there is no record of the production of a work of any considerable merit by a native sculptor. Italy nevertheless claims the honor of having been the seat of the revival in modern times, not of sculpture merely, but of all the imitative arts. During the period known as the dark ages the arts were in some degree kept alive by the monks of the early Greek and Latin churches; but a style and treatment founded on new conceptions of the purposes to which art should be applied and guided by Christianity, had gradually superseded those of pagan artists. The general causes which produced this result are enumerated in the article *PAINTING*. With Nicola Pisano, who flourished in the first half of the 13th century, the authentic history of modern sculpture properly begins, notwithstanding the preceding century had witnessed the production of works of decided originality, if rude and repulsive in comparison with the wonders of the Greek schools. The mission of the sculptor was similar to that of the Greek artists in the archaic and Phidian periods; but unlike the latter, who improved upon established types, he was compelled to have direct recourse to nature as it existed about him, the remains of antique art then extant being too insignificant to afford models, and according in no respect with the character of the age. Hence modern sculpture, and indeed every department of modern art, was at the outset as widely separated from that of the Greek schools, as the religion which inspired it differed from every system which had preceded. Nicola and his son, Giovanni Pisano, were among the earliest to practise sculpture as a separate art, and the distinctive character which it assumed in their hands gave the first decided impulse to its cultivation in Italy. Their works, consisting of bass reliefs on the façades and pulpits of churches in Pisa, Orvieto, Siena, and other Italian cities, exhibit a beauty and simplicity of composition, and a force of expression, which abundantly compensate for technical shortcomings. Their conceptions of nature are naïve and original, and there is scarcely a trace of the influence of the antique in their productions or those of their contemporaries, notwithstanding that their superiority to any preceding artist is supposed to have been acquired only by the study of such ancient sculptures as were preserved in Pisa and elsewhere. The art inaugurated by the Pisani was further developed during the succeeding century by Andrea Pisano, who executed in bronze the oldest door of the baptistery of St. John in Florence; by Andrea Orcagna, the Masucci, and others, whose genius was chiefly devoted to monumental sculpture and the execution of elaborate ornaments, bass reliefs, and small figures on altars. Of the latter kind of work the altar in the chapel of San Michele in Florence, by Orcagna, is a celebrated specimen.

At the close of the 14th century sculpture, under the influence given to modern art by Giotto, who in turn owed much to the example of Nicola Pisano, had attained a considerable degree of perfection; but with the commencement of the 15th, which has been called the golden age of modern sculpture, as the 16th was of painting, it entered upon a grander epoch, the chief production of which was Lorenzo Ghiberti's celebrated bronze doors for the baptistery of St. John in Florence, which not only exceeded every previous effort of modern sculpture, but have remained to the present time a masterpiece of the art of bass relief. Among the competitors for the first door of St. John were Donato di Betto Bardi, better known as Donatello, and Brunelleschi, called by the Italians Filippo di Brunellesco, both of whom were the friends and contemporaries of Ghiberti. Brunelleschi was most distinguished as an architect, but Donatello, by his noble statues of St. Mark and St. George, and other works distinguished by bold conception and vigorous execution, gained a foremost place among modern sculptors. Luca della Robbia is celebrated for his groups of the Virgin and Christ, and other sacred subjects, executed in terra cotta, and hardened by a peculiar process, the secret of which is said to have perished with him. Among other sculptors of the 15th century were Simone, the brother, and Giovanni da Pisa, one of the many scholars of Donatello; the Pollajuoli; Andrea Verrocchio, at one time a painter and the master of Perugino and Leonardo da Vinci; and Andrea Ferrucci; all of whom were chiefly employed on sacred subjects for churches and convents. Toward the close of the 15th century sculpture, in common with the other arts, began to feel the influence of the newly awakened taste for the antique; and religious subjects were succeeded by those suggested by classical history or mythology, the treatment being founded upon the ancient marbles and bronzes which the zeal of the Medici and other enlightened art patrons then first caused to be exhumed. But if the classical mode of representation was appropriate to strictly classical subjects, and the study of the antique of advantage with respect to the technicalities of the art, the introduction of pagan forms and ideas into works of a purely Christian character was calculated to check the healthful development which art had already taken, and to weaken its influence in addressing modern sympathies. A pseudo-classical style, founded on mere imitation, uninspired by the sentiment which influenced the ancient artists, and irreconcilable with the spirit of the age, thenceforth made rapid innovations upon the practice of sculpture, and the art, while in the maturity of its promise, began to decline. At this period the most extraordinary character in the history of modern art produced his masterpieces of form. The works of Michel Angelo Buonarroti are beyond comparison the

grandest efforts of modern plastic art, and his colossal Moses in the monument of Pope Julius II., his monumental statues of Lorenzo and Giuliano de' Medici, and his group called *La Pietà* in St. Peter's, show that the influences of the antique were unavailing to destroy his original conceptions of character and design. Grandeur and energy of expression and action were his chief characteristics, and his intimate knowledge of anatomy enabled him to follow the suggestions of his imagination to an extent attained by no other artist, and which was calculated to mislead or bewilder others brought under his influence, but destitute of his genius. He had numerous followers, whose works, for the most part mannered and exaggerated imitations of their master's style, are now forgotten. Contemporary artists of the 16th century were Jacopo Tatti, called Sansovino, of Venice, who had many eminent scholars; Pietro Torrigiano; Baccio Bandinelli, who restored the right arm of the Laocoön; Benvenuto Cellini, equally distinguished as a sculptor and as a worker in the precious metals; Guglielmo della Porta, famous for his admirable restorations to the Farnese Hercules; and Giovanni da Bologna, a Frenchman by birth, sculptor of the celebrated "Rape of the Sabines" and the bronze statue of Mercury at Florence; all of whom possessed great merit as sculptors, although their works are conceived after a lower ideal than those of the masters of the previous century, and are imitations of the antique. Profuse ornamentation, high finish, illusive effects, and a great elaboration of details engaged the attention of the artist, and nobility of form and force of expression were lost in vain attempts to represent anatomical impossibilities. Giovanni Lorenzo Bernini, born in Naples in 1598, affords an example of this perversion of the principles of the art, and his works, notwithstanding the fertility of imagination and the executive ability which they display, are deservedly considered to violate taste and propriety. Alessandro Algardi, Francesco Mocchi, and other sculptors of the 17th century, exhibited similar characteristics, although in occasional efforts they rose above the spirit of the age. Francesco di Quesnoy (originally Duquesnoy), called Il Fiammingo (the Fleming), deserves mention as an artist of purer taste, who excelled in portraying children. With the commencement of the 18th century sculpture in Italy had degenerated into a purely ornamental art, in which mechanical skill was more appreciated than taste or originality. In the latter half of the century the enlightened efforts of Popes Clement XIV. and Pius VI., and Cardinal Albani, the publications of Winckelmann, and the unearthing of the buried treasures of Pompeii and Herculaneum, had the effect of reviving a love for the antique; and with the appearance of Canova (1757-1822) succeeded an era of purer taste. Some of the early works of Canova

reflect the true antique spirit; but he subsequently cultivated a meretricious gracefulness of form, particularly in his female figures, with a frivolous and ignoble mannerism. Among the successors of Canova have been Tenerani, Fraccaroli, Bartolini, Finelli, Magni, and Vela, the sculptor of the well known statue of Napoleon dying at St. Helena. Their works are gracefully designed, though somewhat feeble and affected, and admirably finished. Giovanni Dupré of Siena (born 1817) rises above academical conventionality, and may be considered the leading sculptor of the time in religious subjects. His *Pietà* for the cemetery of the Misericordia in Siena is his most striking production. Bastianini of Fiesole (died 1868) was also a sculptor of remarkable promise.—The history of Italian sculpture may be considered to describe in general terms the progress of the art in modern times in other European nations. In all of them it probably received its impulse from Italian artists, followed almost similar phases of improvement and decline, was influenced by similar fashions, and has been so slightly modified by national habits or feelings as to render unnecessary any elaborate account of its progress out of Italy. The chief masterpieces of ancient and modern art are still to be found in that country, and thither it is still the custom for sculptors of other countries to resort. In France the earliest names of note are Germain Pilon and Jean Goujon, who flourished in the 16th century. The florid style of Giovanni da Bologna was subsequently followed with considerable success, and in the reign of Louis XIV. Girardon and Puget were the precursors of a long line of sculptors, among whom were Coysevox, Falconnet, celebrated for his equestrian statue of Peter the Great, Guillaume Coustou, sculptor of the famous "Horses of Marly" in the Champs Élysées of Paris, his brother Nicolas Coustou, Pigalle, Bouchardon, Houdon, noted for his fine portrait statue of Washington, Chaudet, and other artists of merit. In the first half of the present century flourished David d'Angers, a great and original artist, author of the sculptures on the pediment of the Pantheon in Paris; Barye, Bosio, Rude, Cortot, Pradier, Lemaire, Duret, Joffroy, Simart, Foyatier, and Préault. Contemporary French sculptors are Guillaume Perraud, Carpeaux, Crauk, Falguière, Gumery, Millet, and Dubois. Sculpture in Spain has since the 16th century been identical or nearly so with that of Italy, except that it has been more exclusively devoted to religious purposes, a practice which led to the manufacture of images of sacred personages colored to represent life and habited in real drapery. The thirty years' war and other disturbing causes checked the development of the art in Germany during the 17th century; and in the 18th we find few sculptors of note besides Andreas Schlüter, who produced the equestrian statue of the Great Elector in Berlin, and Donner.

Within the present century German sculptors have infused a certain amount of healthful realism into their monumental works and portrait statues. Rauch excelled in this particular, and his equestrian monument of Frederick the Great in Berlin is one of the finest works of its class executed in modern times. Other sculptors of note are Dannecker, Schadow, Drake, Schievelbein, Rietschel, Hähnel, Kiss, Schilling, Begas, and Schwanthaler, most of whom have followed a style partaking of the qualities of modern romantic art and of the antique. Denmark has produced in Thorwaldsen an artist who coöperated with Canova in bringing back the severity and simplicity of antique art, and who at the same time had no lack of religious feeling. Until the present century the art was pursued in England principally by foreigners, and the first native sculptor of note was Flaxman, a man of singularly pure ideal conceptions, whose works bear a striking affinity to the antique. His designs from Homer are in this respect among the most remarkable productions of modern art. Next in ability to him was Gibson, who passed a great part of his life in Rome, and cultivated the antique style with considerable success. Other British sculptors of repute are Chantrey, the two Westmacotts, Wyatt, Thomas, Watson, Lough, Macdowell, Bailey, Marshall, Weekes, Thornycroft, Bell, Woolner, and Foley. No sculptures worthy of the name were produced in the United States previous to the time of Greenough (1805-'52), but within the past half century the art has been followed with various degrees of success by a considerable number of Americans. The most promising of these was Thomas Crawford, whose equestrian monument to Washington in Richmond, Va., possesses more than ordinary merit. Powers, for many years a resident of Florence, acquired a reputation by his "Greek Slave;" and Story, Randolph Rogers, and Ward are contemporary sculptors of ability. Besides these may be mentioned Palmer, Brown, Ball, Clevenger, Akers, Bartholomew, Harriet Hosmer, Hart, Rinehart, and Launt Thompson. John Rogers is noted as a successful designer of statuette groups. The sculptured remains of Central and South America, like those of eastern Asia and India, are chiefly of value to the archæologist, and do not illustrate the progress of the art. They are distinguished by vastness of scale and a certain grotesque fancy, and in some instances by a beauty and symmetry of form remarkable in a semi-civilized people.—The most comprehensive work on the history of sculpture is Schnaase's *Geschichte der bildenden Künste* (7 vols., Düsseldorf, 1843-'64; 2d ed. by Lüt-zow and Friederichs, 1866-'75), still unfinished. See also Vasari, "Lives of the most eminent Painters, Sculptors, and Architects" (English translation by Mrs. Jonathan Foster, 5 vols. 8vo, London, 1850-'53); Flaxman, "Lectures on Sculpture," with 52 plates (London, 1829);

Lübke, *Geschichte der Plastik*, with 231 woodcuts (Leipsic, 1863; 2d ed., 1870; English translation by Mrs. Bunnett, 2 vols., London, 1872); Westmacott, "Handbook of Sculpture" (Edinburgh, 1864); Perkins, "Tuscan Sculptors" (2 vols., London, 1864); Tuckerman, "Book of the Artists" (New York, 1867); and Viardot, *Merveilles de la sculpture* (Paris, 1872).

SCUPPAUG, a spiny-rayed fish of the family *sparidae* and genus *pagrus* (Cuv.); it is also called scup and porgy in some localities. In this family the gill covers are shining and scaly, and unarmed; the palate without teeth and the jaws not protractile; the spinous rays of the dorsal and anal fins bare, and received when depressed in grooves at their base; pectorals and ventrals sharp-pointed; branchiostegal rays six; the scales large and thin, broader than long, the centre of growth being near the posterior border. In *pagrus* the molars are rounded and in two rows, and the front teeth conical with a villiform card-like band behind them. There are more than a dozen species in

Scuppaug or Porgy (*Pagrus argyrops*).

the Mediterranean and Red seas, and the East Indian and S. Pacific archipelagos. The common species on the American coast (*P. argyrops*, Cuv.) attains a length of 8 to 12 in.; when first taken from the water it is pinkish or flesh-colored above and silvery below; about the eyes reddish; a narrow green ridge at the base of the dorsal, and one just back of the eyes; iris mostly silvery; dorsal reddish, with the anterior rays silvery; the body is much compressed toward the back, which is high; the lips large and loose; caudal deeply forked; there is a large purple scale at the beginning of the lateral line. The food consists of cuttle fish, crustaceans, mollusks, and sea weeds. It is found from Massachusetts to South Carolina, and is largely used as food in a fresh state. The *P. vulgaris* (Cuv.) of the Mediterranean is about the same size, silvery, with reddish tinges or bars on the back; its flesh is highly esteemed; it was known as the *phagros* by Aristotle, and was placed in the old genus *sparus* (Linn.) until separated by Cuvier; it is not found in northern waters.

SCURVY, or *Scorbutus*, a disease depending upon insufficient and faulty nourishment, which was known to the ancients, but has been more common since long sea voyages have been undertaken. Sea scurvy depends on an impoverished condition of the blood, in which the albumen becomes less easily coagulable and the fibrine less coherent. The most marked symptoms are swollen gums, pale and bloated complexion, lassitude, lowness of spirits, extreme debility, and a tendency to hæmorrhages, which may take place from the intestines, under the skin, or among deeper-seated structures, even beneath the periosteum. Ulceration, sloughing, separation of epiphyses, disuniting of old fractures, and intercurrent diseases of a low type, may be observed. The scorbutic taint, when not manifest as a distinct disease, sometimes complicates other affections. Sea scurvy was formerly the scourge of a seafaring life. In 1593 Admiral Hawkins said that, within his experience, as many as 10,000 seamen had died of scurvy. Lord Anson, in his voyage round the world, at a much later period, lost more than four fifths of his men; and when he arrived at Juan Fernandez, of the 200 men then surviving, only eight were capable of duty. The whole crew of the Spanish ship *Oriflamme* perished in this manner, and the vessel was discovered floating at the mercy of the winds, with the dead bodies on board. Though principally occurring during long sea voyages, it has been seen, in very destructive forms, in besieged cities, camps, prisons, and even among a destitute rural population. Dr. Joseph Jones, a confederate surgeon, estimates that nine tenths of the great mortality in the Andersonville prison was due directly or indirectly to scurvy.—Many causes, such as depressing mental emotions, fatigue, exposure to cold and wet, neglect of ventilation and cleanliness, and insufficient food, undoubtedly contribute to the production of scurvy; but its essential cause is a deficiency of some important constituent of the food. It has not been determined with chemical accuracy what the missing constituent is, though it has undoubtedly a near connection with some of the organic acids, namely, tartaric, acetic, citric, malic, and lactic. But the class of aliments which furnish the substances needed are well known, and there are few diseases which can be more completely cured, or still better prevented, by judicious hygienic management. The aliments which have this power are mostly vegetable, though fresh meat and milk have been found to play an important part in some cases. Salt meat is not a cause of scurvy, except as excluding more nourishing and digestible food. The efficacy of lemon juice as an antiscorbutic seems to have been known in 1609, but it was not till 1795 that, by order of the admiralty, it was regularly supplied to the British navy. Since that time the amount of scurvy has vastly diminished. The lemon juice should be pure, should have 10 per cent. of

brandy or rum added to prevent fermentation, and should be packed in jars, covered with a layer of oil, and sealed. Nearly all esculent vegetables, especially raw and unripe, before the acids have given place to sugar and jelly, are antiscorbutics. Potatoes are among the best. Cabbage, in the form of sour crout, in which acetic acid has been developed, water cress, and onions rank next. Gooseberries and tamarinds are useful; and a decoction of the leaves and bark of a tree, supposed to have been a spruce fir, restored to health the crew of Jacques Cartier in 1535-'6. Several other vegetables are likely to be useful in an emergency, such as sorrel (*Rumex acetosella*), lamb's quarter (*Chenopodium album*), wild artichoke, the American aloe (*Agave Americana*), indigenous in Texas, California, and Mexico, the prickly pear, and the dandelion. Desiccated vegetables may be used, but are less efficient as well as less agreeable than the fresh. Dr. Parkes recommends the issue of vinegar with the daily rations, in addition to the lemon juice, and also the citrates, tartrates, lactates, and malates of potash in bulk, to be used as drinks or added to the food.

SCURVY GRASS, a plant of the mustard family, so called originally on account of its supposed antiscorbutic properties, *Cochlearia officinalis* (Lat. *cochlear*, a spoon, from the shape of the leaves), found on the seacoast of Great Britain and all around the Arctic circle. It is a low, smooth annual or biennial, with a rosette of heart-shaped root leaves; flower stalks 6 to 12 in. high, with numerous small white flowers. The odor of the leaves when bruised is unpleasant, and the taste acrid and bitter; it is sometimes eaten as a salad, but more from some

Scurvy Grass (*Cochlearia officinalis*).

supposed medicinal effect than for its palatableness. It is sometimes cultivated in Europe.—The plant called scurvy grass in Pennsylvania and southward is a native of this country as well as of Europe, where it is known as winter cress, *Barbarea vulgaris*; it is common

in low grounds, has dark green leaves, and produces its yellow flowers in early spring. A small variety of it (formerly called *B. præcox*) is sometimes cultivated, and is sold in the markets as water cress, to which it is much inferior in flavor.

SCUTARI. **I.** A town (Turk. *Uskudar*; anc. *Chrysopolis*) of Asiatic Turkey, on the Bosphorus, opposite Constantinople and the largest suburb of that city; pop. about 70,000. It is built on several hills, and has an imperial palace, eight mosques, a convent of howling dervishes, celebrated Turkish burial grounds, and an English cemetery, where about 8,000 soldiers are buried, and which contains a large obelisk by Marochetti with an inscription in several languages. Near the cemetery are barracks, in the building which during the Crimean war was used as a hospital, celebrated through Florence Nightingale's labors. Scutari is a great centre of traffic between the capital and the Asiatic provinces. **II.** A fortified town (Albanian, *Skodra*; Turk. *Iskenderieh*) of European Turkey, in N. Albania, on the river Boyana, at the S. E. extremity of the lake of Scutari, 15 m. from the Adriatic coast; pop. about 25,000. It is the see of a Greek bishop. About half the population are Catholics under the united archbishopric of Antivari and Scutari, the rest being Greeks and Mohammedans. It has manufactures of cotton goods and firearms, and ship yards, and considerable trade is carried on. On an adjacent lofty hill is a citadel.—The lake of Scutari or Zanta (anc. *Labeatis*), on the S. W. border of Montenegro, is about 18 m. long from N. W. to S. E. and 6 m. wide. It contains small islands, receives most of the streams of Montenegro, the principal being the Moratcha, and communicates with the sea by the river Boyana. It abounds with fish, especially of the carp family.

SCUTIBRANCHIATES, an order of gasteropod mollusks, so named by Cuvier because the gills or branchiæ are protected by a *scutum* or shield, as in the *haliotidæ* or ear shells.

SCYLLA. See **SCIGLIO**.

SCYTHE, and **Sickle**, long knives with a curved edge, the former commonly used for mowing grass, bushes, &c., and the latter, called also a reaping hook, for cutting grain. These implements in ancient times were also employed as weapons. In ancient Roman cameos they are depicted in the various forms in which they were employed under the general name of *falsæ*; as the *falsæ messoria*, the crooked sickle, still used for reaping grain; *falsæ fenaria*, the long scythe for mowing grass, constructed with a handle at right angles to the blade, very much as at present; *falsæ vinatoria*, *arboraria*, *silvatica*, &c., the pruning knife, bill hook, bush scythe, &c. The implement was a symbol of Saturn, the *senex falcifer*, personifying time, who cuts down and destroys all things as with a scythe. As a weapon the scythe was also made in several forms. The

sword with the curved edge was the *falcatus ensis*; and in the shape of a short hooked knife, the handle terminating beyond in a dagger, it was made of convenient use for one hand, or attached to the end of a pole. In another form, which was used by the Assyrians, Medes, Persians, Gauls, and Britons, the long crooked scythe blades were fastened to the axles of their chariots or to the fellos of the wheels, and were thus made to cut down those among whom the chariots were driven. In modern warfare scythes have been used in close combat, and make a formidable weapon.—As agricultural instruments, there was little difference in the forms of the ancient scythes and sickles from those of the present time, and they appear from the representations of them to have been as well adapted for their uses as any made up to the 17th century. The same forms appear in the illustrations of Strutt in his "Manners and Customs of the People of England," and were there in use more than ten centuries ago; but the snath or handle was straight, and was furnished with only one short holding piece. Among the earliest recorded improvements is the stiffening of the back edge by welding to it a strip of iron. This was also one of the earliest American mechanical inventions, being made by Joseph Jenks, who established iron works in 1646 on the Saugus river in Lynn, Mass., and in May, 1655, received from the legislature a special grant or patent running seven years for this improvement. In the notices of early iron works in New England, scythes are generally named among the most important products. Among the manufacturers especially noted for this and similar productions was Hugh Orr, a Scotchman, who emigrated to Bridgewater, Mass., in 1738. His son Robert Orr established the present mode of forging scythes with the trip hammer. The business has since been largely conducted in Sutton, Worcester co., and also in several towns in Maine and New York; but it is gradually disappearing before the introduction of mowing and reaping machines. In England the manufacture has been important for the last 300 years, and has been particularly successful in the N. extremity of Derbyshire, extending about 6 m. S. from Sheffield. It was established there by a party of Flemings who were driven from the Netherlands, the scythe makers among them settling in the parish of Norton and the sickle makers in the adjoining one of Eckington. The best of these tools are still made in this neighborhood, and in Bristol and Dudley.—Scythes for cutting grain, having a framework of wooden bars parallel with the blade for laying the grain straight, are called cradles.

SCYTHIA, in ancient geography, a vast area, of indeterminate boundaries, in eastern Europe and western Asia. Its native population, according to Herodotus, called themselves Scythi. The name Scythians is found in a verse of Hesiod, as given by Strabo, but it appears

from internal evidence that it is an interpolation, or a correction of some copyist. Homer speaks of races who were "milkers of mares and cheese-eaters," which description agrees with what Hesiod says of the people he mentions. Herodotus describes Scythia as a square area, extending 4,000 stadia (nearly 500 m.) on every side, the southern boundary being the coast from the mouth of the Danube (not including the Tauric Chersonesus) to the sea of Azov (Niebuhr), or to the mouth of the Don (Rawlinson). Scythia, as described by him, probably comprehended the whole territory from the E. Carpathians to the lower Don. On the north were the nations called Agathyrsi, Neuri, Androphagi (cannibals), and Melanchlæni (black-coats). The Sarmatians, a Scythic tribe, subsequently gained the ascendancy, and their name was thereupon given to the territory comprised in the Scythia of Herodotus. (See **SARMATIA**.) Afterward the Greeks applied the name to the Asiatic region N. of the Oxus and Jaxartes, from the Caspian to the confines of China, and divided it by the northern Imaus range (the Thian-shan) into Scythia intra Imaum and Scythia extra Imaum.—Herodotus visited the Greek settlements on the northern shores of the Euxine, and describes the Scythians as nomadic tribes, living on animal food, keeping large troops of horses, and excelling in horsemanship and archery. Hippocrates describes them as gross and fleshy, with loose and yielding joints, and little hair. It was customary for a Scythian to drink the blood of the first man he slew in battle, and to preserve as trophies the scalps and skins of the enemies he overthrew. They entombed their kings amid sacrifices of men and beasts, and put great faith in soothsaying and magic arts. They were the successors of the Cimmerians in the order of migration westward, and invaded the Median empire near the close of the 7th century B. C. (See **MEDIA**.) Cyrus is said to have fallen in a battle against the Scythian Massagetæ in Asia, and Darius I., who led a vast expedition against the Scythians in Europe through Thrace, was compelled to retreat with severe loss. The Parthians too are believed to have been of Scythic descent. The hordes which about 200 B. C. came from the western confines of China and overran parts of Turkistan and modern Persia, were also Scythians; they turned toward India, and a portion of them founded a settlement known as Indo-Scythia. The names of the principal tribes engaged in the Scythian incursions, as far as they have come down to us, are Sacæ (often used in a wide sense, and sometimes applied to the Scythians in general), Massagetæ, Dahæ, Tochari, Asii or Asiani, and Sacarauli.—Some scholars maintain that the Scythians were Turanians, others that they were Indo-Europeans; Rawlinson thinks that the Greeks and Romans applied the name to any nomad race, whether Indo-Europeans or Turanians.—For the family of languages to which many phi-

logists apply the term Scythic, see **TURANIAN RACES AND LANGUAGES**.

SCYTHOPOLIS, an ancient town of Palestine, about 12 m. S. of the sea of Galilee, and 4 m. W. of the Jordan. The village now occupying its site is called Beisan, preserving its Scriptural name Bethshean or Bethsan. It is supposed that its classical name was given it after the invasion of the Scythians, because a large number of Scythians had permanently settled in it. The Philistines fastened the corpses of Saul and his sons to the walls of Bethshan, which, though belonging to Manasseh, was never really a Jewish city. Scythopolis was one of the cities of the decapolis. Pompey devastated it, Gabinius rebuilt it, and Saladin burned it. Ruins of temples, a theatre, and walls are scattered over the neighborhood of the present village.

SEABURY. **I. Samuel**, an American clergyman, born in Groton, Conn., Nov. 30, 1729, died Feb. 25, 1796. He graduated at Yale college in 1748, studied medicine in Scotland, and then theology, and was ordained in London in 1753. He became rector of Christ's church, New Brunswick, N. J., in 1757 of Grace church, Jamaica, Long Island, and in 1766 of St. Peter's, West Chester, N. Y. During most of the war of the revolution he resided in the city of New York, being a royalist. He was consecrated bishop of Connecticut at Aberdeen, Nov. 14, 1784, and was chosen rector of St. James's church, New London. He took part in revising the prayer book and framing the constitution of the church which was adopted in 1789. Three volumes of his sermons were published in 1791-'8. **II. Samuel**, an American clergyman, grandson of the preceding, born in New London, Conn., June 9, 1801, died in New York, Oct. 10, 1872. He was ordained deacon in the Protestant Episcopal church, April 12, 1826, and priest in July, 1827. He was a missionary for a time at Huntington and Oyster Bay, Long Island, whence he removed to Hallet's Cove (now Astoria). In 1831 he removed to New York, and for 18 years was editor of "The Churchman," and from 1838 to 1868 he was rector of the church of the Annunciation. He was chosen professor of Biblical learning in the Episcopal general theological seminary in June, 1862. He published "The Continuity of the Church of England in the Sixteenth Century" (1853); "Discourses on the Supremacy and Obligation of Conscience" (1860); "American Slavery Justified" (1861); and "The Theory and Use of the Church Calendar" (1872). After his death appeared "Discourses Illustrative of the Nature and Work of the Holy Spirit, and other Papers," edited by his son (1874).

SEA CAT, the common name of the cartilaginous fishes of the order *holocephala* and family *chimæroidæ*. They seem to form a group intermediate between the sturgeons and sharks;

the dorsal cord is continuous, with cartilaginous neural arches and transverse processes; the skull is short and rounded, produced on each side into a process to which the lower jaw is connected instead of to an *os quadratum*; the upper jaw and palate are fused with the skull, without traces of suture; the upper jaw has four broad plates or teeth, and the lower two; the eyes very large and without lids; nasal cavities very large and convoluted, opening on the under side of the snout in front of the mouth, which is small; the branchiæ are not fixed by their outer margin, and are covered by a small operculum, adhering to the hyoid arch, with only a single aperture on each side behind the head, communicating interiorly with five branchial sacs opening separately into the pharynx; there is no air bladder, and the intestine has a spiral valve. The skin is covered with placoid granules; between the eyes is a fleshy club-shaped process, with serrated edge and ending in a spine, which somewhat resembles a crown, and has given rise to one of its popular names, "the king of the herrings." The ventrals are abdominal, the anal small, the pectorals powerful, and the tail heterocercal; the anterior dorsal is short, triangular, with a strong spine for the first ray, and is placed over the pectorals. They are oviparous, the large eggs being enclosed in a leathery capsule; the males have trifold claspers.—The northern sea cat (*chimæra monstrosa*, Linn.) has a conical snout, the dorsals contiguous and reaching to the end of the tail, which is prolonged into a slender filament; the body is elongated and shark-like; the eyes have a greenish pupil surrounded by a white iris, and they shine, especially at night, like cats' eyes, whence the common name; the color is silvery with brown spots; the tail is nearly as long as the body. It attains a length of 3 or 4 ft., and is found in the North sea and northern Atlantic, where it pursues the shoals of herring and other mi-

wounds.—In the southern sea cat (*callorhynchus australis*, Gronov.) the snout ends in a gristly appendage, bent backward at the end so as to resemble a hoe; the anterior dorsal is very far forward over the pectorals, the second over the ventrals and reaching to the caudal, and the tail does not end in a filament. It is of about the same size as the northern animal, and silvery, tinged with yellowish brown.

SEA COW. See MANATEE.

SEA CUCUMBER, one of the popular names of the *holothuria*, the highest order of the echinoderms, which are the highest class of ra-

Sea Cucumber (*Holothuria lutea*).

diated animals; the name is derived from their generally elongated and more or less cylindrical and warty form; they are also called sea slugs from their vermicular mode of creeping. The body is rather soft, with a leathery skin sometimes furnished with calcareous plates or granules without spines; the mouth is at one end and the cloacal opening at the other, the former surrounded by branching and retractile tentacles supported on an osseous ring which forms the rudiment of an internal skeleton; the ambulacra (feet) or suckers are arranged usually in longitudinal rows on the sides of the body, alternating with spaces having no such apparatus, and corresponding to the spiny rows of star fishes and sea urchins; motion is effected principally by these suckers, the mouth forward. By the introduction or ejection of water at the posterior extremity the body may be made to assume great variations in length and width, and the general appearance externally is more that of an annelid than a radiate. Some of the genera (as *synapta*) have cutaneous anchor-like hooks by which they attach themselves, each inserted obliquely under a small subcutaneous scale perforated by a canal. The muscular layer under the skin is very thick, and so powerful in its constrictions that the animal can discharge all its viscera through the

Northern Sea Cat (*Chimæra monstrosa*).

gratory fish; it also feeds on jelly fishes and crustaceans. The flesh is tough, but the Norwegians use the eggs as food, and employ the oil of the liver in diseases of the eyes and for

mouth. They have a well developed œsophageal ring, which sends off nerves to the body and tentacles; the intestinal canal is very long, retained in place by a kind of membranous

Synapta Duvernœi.

mesentery, and generally unsymmetrical; they have a distinct vascular system, but no heart; the tubes for the water for respiration are much branched, and open from the cloaca; respiration is also effected partly by the tentacles around the mouth, which communicate with the aquiferous system, and by the water introduced into the visceral cavity. The feet are either in five rows as on the ribs of a melon, or only on the lower surface, or on a kind of ventral disk; their motions at the bottom of the sea are aided also by the oral prehensile tentacles. The quinary system prevails among holothurians as among other echinoderms. The sexes are distinct; some multiply by fissuration, but most by means of eggs; in the first form the young has an oval ciliated body, like an infusorial animalcule, without external organs or distinction of parts; in the next larval change the organs are developed, at first in a bilateral manner (according to Müller), and then pass into the radiated type by a process of internal gemmation, receiving new locomotive organs in the ciliated fringe as they pass into the pupa form, from which the true echinoderm is developed.—The old genus *holothuria* (Linn.) has been variously subdivided. They are generally small on the New England coast, but attain a large size in the bay of Fundy and on the banks of Newfoundland; on the mud flats of the Florida reefs they are sometimes seen more than a foot long and 3 or 4 in. in circumference. All along the American coast is found the *sclerodactyla Briareus* (Ayres), from 3 to 6 in. long, dark brown, with 10 very branching tentacles; it lives on muddy bottoms in shallow water among the roots of *zosteræ*. The *Cuvieria Fabricii* (Dub. and Kor.;

H. squamata, Fabr.) is about 3 in. long, and bright brick-red, the color being readily imparted to alcohol and even to water; it is scaled and granulated above, and has 10 tentacles; it is generally caught on hooks, and occurs on the coast of New England. The *chirodota arenata* (Gould) is 5 to 6 in. long, club-shaped, ending posteriorly in a tube about the size of a crow quill; the color is light drab, with calcareous granules; it is found on our beaches after storms, and lives in shallow water. The *botryodactyla grandis* (Ayres) is very abundant in the bay of Fundy and on the banks of Newfoundland, and attains a length of 6 to 8 in.; when boiled it is very palatable. From researches made on the American coast it appears that the laminarian zone just below low-water mark is the favorite residence of holothurians, though a few occur in deep water. Those found in shallow water are the most common. The sea urchins live in deeper water, and the star fishes are the lowest both in habitat and in the radiated scale. The breeding season here seems to be the winter and spring. For a description of the 8 genera and 13 species of the American coast, all of which are different from those of Europe, see "Proceedings of the Boston Society of Natural History," vol. iv. (1851-'2), where Dr. W. O. Ayres has carefully compared them.—Among the European species are the *H. (psolus) phantapus* (Linn.), with an almost scaly envelope, and the feet of its central disk arranged in three series; the *H. squamata* (Fabr.), a small species, with the lower surface flat and soft with a great number of feet, and rough and scaly above; and the *H. tremula* (Gmel.), of the Mediterranean, blackish, bristled above, with numerous feet below, and 20 branched tentacles, which grows to a foot in length, and is one of the species eaten by the Italian fishermen. Several species of holothurians are collected in the East Indies for food, under the name of *biche de mer* or *tripang*, the taking and preparation of which employ great numbers of the Malays and Polynesians; the best are found on reefs of mixed coral and sand in the Feejee group in one or two fathoms of water, and are obtained by diving. They are boiled in their own liquid, then dried on stages in large heated houses, and meet with a ready sale at high prices in the Chinese markets as ingredients for rich soups. For an account of the mode of preparation, see vol. iii. of the "Narrative of the United States Exploring Expedition," under Capt. Wilkes, pp. 218-222, with a plate. Dr. Karl Semper has described and figured in great detail the holothurians of the Philippine islands in his *Reisen im Archipel der Philippinen* (3 vols., Leipsic, 1867-'72). See also Wallace's "Malay Archipelago" (1869).

SEA ELEPHANT. See SEAL.

SEA FAN, a name popularly given to the alcyonarian polyps of the family *gorgonidae*, from their minutely branched and fan-like appearance. They are composed of a horn-like internal central axis, having sometimes in its sub-

Sea Fan.

stance a little carbonate of lime, but never enough to give them a coral-like rigidity. The external covering is gelatinous, tenacious, and sometimes almost fleshy, secreted by numerous cylindrical, short, laterally connected polyps. The branches rise irregularly, and are joined together by a network. They live in all seas and in deep water; several species, 4 or 5 in. high, are found on the New England coast, but in the tropics they attain a height of 2 or 3 ft. The sea fan of the West Indies (*gorgonia flabellum*, Linn.) attains a height and width of 2 ft.; it is reddish or yellowish, of delicate texture and branching form.

SEA FOX. See SHARK.

SEA HOG. See PORPOISE.

SEA HORSE. I. See WALRUS. II. An osseous fish of the order lophobranchs (with tufted gills), of the family of pipe fishes, and of the genus *hippocampus* (Cuv.). The ordinal and family characters have been described in the articles LOPHOBRANCHS and PIPE FISH. In the present genus, which includes several species, the snout is prolonged and the head elevated posteriorly, somewhat resembling a miniature horse's head, the ears being represented by a spiny coronet on the occiput; the orbits, pectoral ring, and the other rings of the mailed body are more or less spiny; the tail is without a fin and prehensile, and by means of it they suspend themselves to sea weeds and other submarine objects; the eyes are prominent, and can be moved independently of each other, and in opposite directions; the pouch in which the males carry the eggs till they are hatched opens at the commencement of the tail; the ventrals are absent, and the pectorals very small and just behind the head; there is a single short dorsal on the middle of the back,

whose edge has a spiral motion; the females have a small anal; the mouth is terminal and without teeth. They inhabit all parts of the temperate and especially of the tropical oceans; the food consists of minute marine animals, especially ova; a kind of hibernation has been observed in the Mediterranean species by Rusconi; they swim vertically, with the tail ready to wind around any object they meet. There is one species in the British seas, the *H. brevirostris* (Cuv.), 6 in. or more in length, with much compressed, short, and deep body, divided by longitudinal and transverse ridges, with tubercles at the line of intersection; the snout is comparatively short; the color is pale ashy brown, with iridescent tints about the head. De Kay describes the *H. Hudsonius*, 3 to 6 in. long, from the coast of S. New Eng-

Sea Horse (*Hippocampus brevirostris*).

land and New York; it is yellowish brown, with 12 rings in the body and 36 in the tail. Other species are found in the Mediterranean, and more abundantly in the East Indies.

SEA KALE, a cruciferous plant, *crambe maritima* (Gr. κράμβη, a kind of cabbage), which grows upon the western coasts of Europe and on the Baltic and Black seas, and has long been cultivated in European gardens. Sea kale is a perennial with a long fleshy root; the root leaves are roundish, 6 to 12 in. across, thick, wavy, and often lobed on the margin, and of a peculiar grayish green; the flower stalk is 2 to 4 ft. high, branching, and bears loose panicles of white flowers which have a strong odor of honey; the pod, about the size and shape of a cherry stone, contains but one seed. The wild plant has long been used as a pot herb, and was eaten by the ancient Romans; its cultivation in England dates back a little more than 100 years; it is now held in high esteem there, and is cultivated for market. In this country it is almost unknown, even in private gardens. Those who live upon the shores

where it grows wild cook the leaf stalks and midribs of the leaves, after peeling them; but when cultivated it is so managed that the buds as they push shall be blanched, and the edible portion is the tender, undeveloped leaves. The plant is raised from seeds, the seedlings remaining a year in the seed bed, or from cuttings, 2 to 4 in. long, of the roots of old plants, started in spring on a hotbed. Either year-old seedlings or plants from cuttings are set out in well enriched soil, 2 ft. apart, and the rows 3 ft. distant. On the approach of winter the plants are covered with 8 or 10 in. of sand or leaf mould, so that the shoots in forcing their way up through this in spring will be blanched and tender; when the tip of the shoot reaches the surface the blanching material is drawn away and the shoot cut at its junction with the

Sea Kale (*Crambe maritima*). Blanched Young Shoots.

root. In England, one method of blanching is to use pots or cylinders of earthenware, taller in proportion than flower pots, or wooden boxes. By surrounding the pots with fermenting manure the plant may be forced.

SEAL (Ang. Sax. *seol*), an aquatic carnivorous mammal, the type of the family *phocidae*, constituting the old genus *phoca* (Linn.), which has been variously subdivided. The group of seals is at once distinguishable from other mammals by the structure and arrangement of the limbs; the toes of all the feet are included almost to the end in a common integument, converting them into broad fins, the bones being to a great extent within the skin of the trunk, and the tips armed with strong non-retractile claws; the hind feet are thrown out backward, nearly horizontally, the very short tail being between them, and are the principal agents in swimming and diving; the fore paws when swimming are applied close to the body, and are used only in turning about. The body is cylindrical, tapering gradually backward; the head is small and rounded, and the neck short; the skin has an under woolly down, over which is a covering of long, smooth, and shining hairs, shedding water by an oily secretion, and offering no resistance in swimming; between the

skin and muscles is a layer of fat, as in cetaceans, giving that plumpness to the body expressed in the common saying "as fat as a seal." The skull is thin, which renders the head light in the water, in the smaller species without the crests for muscular origins usually seen in carnivora; the face short and broad; zygomatic arches perfect and strong; anterior nasal opening not terminal, and in some directed almost vertically for facilitating respiration when the animal comes to the surface; the tentorium separating the cerebrum and cerebellum is formed wholly from the occipital bone; the orbits are continuous with the temporal fossæ, and the skull is very narrow between them, the cranial cavity seeming like a box shut off from the facial portion of the head; the lower part of the occipital bone is broad and thin, with an oval opening in the young in front of the great foramen covered with membrane, but closed by bone in the adults, and the condyles are much larger than in other carnivora; the infraorbital foramina are very large, for the exit of the branch of the fifth pair of nerves, which supplies the sensitive whiskers; the nasal bones are very short. The incisor teeth are small and pointed, the canines not generally very projecting, but much worn, and the molars with laterally compressed crowns, sharp cutting edges, many-pointed, and usually single-rooted; the number varies in the different genera. The cervical vertebræ are short, the dorsals and pairs of ribs 15, and the lumbar 5 (in the common seal), the caudals very imperfectly developed, the anterior portion of the sternum prolonged far up the neck and movable, the scapula small with a moderate and nearly central spine, and the coracoid and clavicles absent; the bones of the forearm short, wide, and flattened; the femur at a right angle with the spine and the leg, very short and comparatively immovable, giving greater freedom of motion to the rest of the limb; tibia and fibula long and flat, the former with a double curvature; metatarsal bones and toes long and slender, and the foot wide and paddle-like. The mouth has thick fleshy lips, with many long, knotted, and exceedingly sensitive bristly whiskers with nerves from the fifth pair; the tongue rough and bifurcated at the end; nostrils capable of being completely closed under water; external ears in most merely small valves which close the auditory opening; the eyes (with nictitating membrane) large, full, bright, and expressive of great intelligence; brain large, and with many convolutions; mammae two or four, ventral, near the umbilicus, enclosed in folds of the skin; the intestinal canal is very long for a carnivorous animal; the posterior vena cava, close to the liver, has a large sac or sinus which receives five hepatic veins, serving to retain a portion of the blood from the heart while the animal is under water; the *foramen ovale* in the heart and the *ductus arteriosus* are often found pervious; the stomach is elongated, and has a vil-

lous coat; the right lung is two-lobed, and the left undivided; the kidneys are divided each into 120 to 140 parts like a bunch of grapes; the testes are permanently retained within the abdomen. The crystalline lens is more spherical than in land animals, and the sclerotic very thick in front and behind, and thin in the middle, allowing a change of its antero-posterior diameter by compression of the muscles to suit aquatic and aerial vision; the tapetum is remarkably brilliant. They live in the arctic and antarctic seas, near the coasts, and often at the mouth of rivers, preying upon migratory and other fish, crustaceans, and cephalopod mollusks. They are gregarious and migratory, fond of particular spots, leaving the coldest arctic regions in winter for milder seas; the herds are usually of the same species, or when different each species keeps by itself, rarely fighting with the others. Most are polygamous, each male having three or four females, forming small families; gestation lasts nine or ten months, and one or two young are born at a time, which are tenderly cared for; parturition and lactation occupy two or three months, in autumn, winter, or spring, which are passed on shore, the food being such as can be picked up on land or near the coasts, even from the vegetable kingdom; both sexes at this time grow very lean. They are fond of crawling out of water upon rocks, beaches, and ice floes, for the purpose of basking in the sun, always keeping a good lookout, and plunging into the water at the approach of an enemy; they never go far from their favorite element. They are playful, but at times fight fiercely, as in the breeding season; their bite is severe, and the wounds made by their teeth are not disposed to heal readily either on their own or the human body; some of the larger species are very powerful. The voice is a kind of snapping bark, which, with their canine expression of face, has given them the name of sea dogs. They can remain under water 20 minutes or longer; their animal heat is among the highest found in mammals. They swim with considerable speed, and are most expert divers; their movements on land are awkward and laborious, consisting of a series of short jerking leaps forward by means of the powerful muscles of the back, assisting themselves occasionally, as in climbing rocks and ice, by the anterior limbs; they can advance more rapidly on the ice, by a vertical motion of the spine, somewhat in the manner of a caterpillar, rendered possible by the short spinous processes, large and elastic intervertebral cartilages, and the uncommonly strong spinal muscles. The senses of smell and sight are very acute. They are easily tamed, affectionate, and docile; at zoological gardens they are taught to sit erect, to bow, kiss the hand, pretend to be asleep and to snore, turn the crank of an organ, shoulder a gun, shake hands, and perform other similar simple tricks; in captivity they are much disposed to be drowsy and almost

lethargic. Few animals are more tenacious of life than seals, and the most needless cruelties used to be practised in their capture; now the larger species are generally killed at once with the lance thrust into the heart, and the smaller ones are stunned by a blow on the nose from a long-handled hammer, with a sharp spike on the opposite side to hook into the skull. The Esquimaux hunt them in light boats with lances, or spear them at holes in the ice where they come up to breathe; to them the seal supplies food, oil for light and warmth, skins for clothes, boots, utensils, tents, and boats, sinews for thread and lines, and membranes for under garments and window coverings. The oil is of superior quality, and, if prepared from the fresh animals, is transparent, free from odor, and not unpleasant to the taste; the skin, by a peculiar process of Esquimaux tanning, makes a water-proof leather.—As articles of commerce seal skins are of two kinds, hair skins and fur skins; the former are used for making garments, the latter, now chiefly from Alaska, for finer purposes; all seal skins, however, have a mixture of coarse hairs and finer fur. Millions of skins have been used in Europe and in this country, and thousands of tons of shipping are employed in their capture. Large herds of seals of various species, especially the Greenland and hooded seals, are found on fields of floating ice, called seal meadows; on these the hunters try to surprise them when sleeping, killing the young with clubs and shooting the resisting adults. The seal fishery is extensively carried on from Newfoundland, in sailing vessels of from 50 to 200 tons burden, each manned by from 25 to 90 men; recently steamers have also been employed, ranging from 175 to 450 tons, with from 100 to 200 men each. The seals are taken on the ice off the E. and N. coasts of the island; the season lasts from the first of March to the close of May. The principal species taken are the harp and hooded seals, chiefly the former; two other varieties are also taken in Newfoundland, the square-flipper seal, a large species, and the dotard or native seal, which never leaves the island; the skins of the latter are more valuable than those of the other species, being spotted, and are much used for trunk covers, coats, gloves, &c. The fishery was not prosecuted by Newfoundlanders prior to 1763; in 1787 4,900 seals were taken from the ice, and the oil extracted; in 1871 there were 201 sailing vessels and 13 steamers employed, with an aggregate crew of 9,791 men; the number of steamers is increasing. The exports of seal skins from Newfoundland between 1838 and 1848 varied from 400,000 to nearly 700,000 annually; for the exports of oil and skins from 1868 to 1872 inclusive, see FISHERIES, vol. vii., p. 234. (See also NEWFOUNDLAND.) Many seals are taken in early spring at the Magdalen islands and on the Labrador coast among the floating ice, and also by nets set across narrow channels. Be-

sides man, the seal has to guard against bears on land and on the ice, and against sharks and carnivorous cetaceans in the water.—In the genus *phoca*, as restricted by modern naturalists, the dental formula is: incisors $\frac{1}{2}$, canines $\frac{1}{2}$, and molars $\frac{2}{1}-\frac{2}{1}=32$; the molars have three or four triangular cusps, all except the first with double roots, and placed obliquely along the jaw; the posterior margin of the palate is acutely and deeply notched, and the palatal foramen is on the maxillary bone. The group to which the common seal belongs was named *callocephalus* by F. Cuvier, on account of the fine shape and large size of the cranium and the shortness of the face; the brain is nearly as large as that of the most intelligent monkeys. This species—the *P. (C.) vitulina* (Linn.), the *phoque commun* and *veau marin* of the French, the *Seehund* of the Germans—attains a length of 4 to 6 ft.; the color varies much, but is generally brownish above and yellowish white below, variously mottled, and sometimes pied and marbled. It is common in the European seas, especially those washing the northern countries; it is fattest in spring; a single large animal will yield from 8 to 12 gallons of oil excellent for lamps; the leather is used for boots, and the hide for caps, trunk covers, &c.; the matter which lubricates the hair has a penetrating and offensive odor. Along the New Brunswick coast this species, which is called there the harbor seal, is often seen in summer; the fur is very handsome, and is highly prized by the Micmac Indians; it is also common all along the New England shore. The Greenland or harp seal (*P. [C.] Groenlandica*, Müll.) is about 6 ft. long; the males are grayish white, with the face and a broad lunate mark on the back and sides black; the females are brownish with blackish spots, and the young snow-white; the molars are in a straight line, with a small interval between them and the anterior tubercle obsolete; the posterior margin of the palate almost directly transverse. They are found in herds on the coast of Greenland on floating ice, rarely venturing on shore or shore ice; they are sometimes floated to the coasts of Great Britain,

Common Seal (*Phoca vitulina*).

and are not uncommon on those of Labrador and Newfoundland. This is the most important of all to the Esquimaux, who harpoon it

from their kaiaks; the oil is the best and most abundant in this species, and the skins form an important article in the fur trade. The young

Greenland Seal (*Phoca Groenlandica*).

are born in spring. A species of seal (*P. Caspica*, Pall.), about the size of the common seal, occurs in the Caspian sea, the sea of Aral, and Lake Baikal; it affords an excellent oil, to obtain which many thousands are annually killed.—In the narrow-muzzled seals belongs the genus *stenorhynchus* (F. Cuv.), with the incisors $\frac{1}{2}$, pointed, and the molars $\frac{2}{1}-\frac{2}{1}$, divided into three to five long points, conical, somewhat hooked, and usually two-rooted; the snout is long and narrow, and the claws, especially on the hind feet, very small, hence called *leptonyx* by Wagner and Gray. The leopard seal or sea leopard (*S. Weddellii*, Less.; *L. leopardinus*, Wagn.) is 9 or 10 ft. long, spotted above somewhat as a leopard, whitish on a grayish brown ground, and yellowish below; the head is long and small, the neck long and tapering, and the hair soft and thin; it frequents the frozen seas of the southern hemisphere, about the South Shetland and South Orkney islands. In the genus *pelagius* (F. Cuv.) the snout is broad and long; the number of teeth is the same as in the last genus, but the incisors are indented and shut into each other, and the molars are thick, compressed toward the crown, with rudimentary points and central conical cusp. The white-bellied or monk seal (*P. monachus*, F. Cuv.) grows to a length of 8 or 10 ft.; it is shining dark brown above, spotted with gray on the neck and head, and the lower parts and portions of the sides white; eyes large and ox-like; it is gentle, easily tamed, intelligent, and affectionate; it is found in the Adriatic sea and on the coast of Sardinia, and was the one best known to the ancients; its skin was believed by the old Romans to be a preservative against lightning, and tents were made of it under which they took refuge in thunder storms.—In the genus *stematoprus* (F. Cuv.) or *cystophora* (Nilss.), the incisors are $\frac{1}{2}$ and conical, the canines large, and the molars $\frac{2}{1}-\frac{2}{1}$, simple-rooted, compressed and striated, with three lobes and many small indentations;

the generic name is derived from a soft crown-like appendage from the nose to the back of the head. The hooded or crested seal (*P. leonina*, Fabr.; *S. cristatus*, F. Cuv.) attains a length of 7 or 8 ft.; the color is dark brown above with gray spots, the young being light-colored; they have on the head a membranous and muscular sac covered with hair, divided into chambers by a prolongation of the nasal septum; when the nostrils are closed this can be inflated with air; the skins are among the most common in the market. They are fond of the ice islands of high northern latitudes, coming down to the coast of Labrador; they are polygamous, fierce when wounded, and fight furiously with each other. The appendage on the head may be, as the fishermen suppose, a reservoir of air for use during submersion, or

Hooded Seal (*Stenmatopus cristatus*)

an accessory to the organ of smell, as its vascular nature seems to indicate.—In *macrorhinus* (F. Cuv.) the incisors are far apart, hooked like small canines, the central ones the smallest; the canines are strong tusks; the molars have simple roots, the crowns appearing like nipples on a rounded base; the number of teeth is the same as in the preceding genus; the forehead is very prominent, the bones as in the elephant for supporting a trunk; the nasal bones are very short, and the maxillaries long with a very large nasal opening between them. The bottle-nosed seal or sea elephant (*M. morunga*, Gray) *proboscideus*, F. Cuv.) is the largest of the seal family, attaining a length of 25 ft. or more, with a circumference of about 16 ft., the size as well as the proboscis justifying the popular name. The males are generally dark grayish blue or brown; they can elongate the muzzle to a foot in length; the females are dark olive-brown above and yellowish below, and do not have the nasal appendage; they are polygamous, and the males in the breeding season are very pugnacious; they have four fingers and a short thumb on the fore limbs with perfect nails, and the hind toes nailless. The hair is rather coarse, but the thick skin is in much request for harnesses; a single animal will yield 14 to 15 bbls. of blubber, from which the oil is obtained as in the whale; the oil is clear, without bad

odor or taste, and burns slowly and without smoke; in England it is used for softening wool and in the manufacture of cloth; the salted tongues are esteemed as food. They are found in large herds on the shores of the islands of the antarctic seas, going north in winter to the coasts of Patagonia, remaining between lat. 35° and 55° S.; they prefer sandy and desert beaches, in the neighborhood of fresh water, in which they like to wallow. They never attack man unless brutally treated by him; from indiscriminate slaughter they are now very scarce in their former accessible haunts. This species is half as large as the Greenland whale, and very much larger than the largest elephant.—The family of *otariadae* or eared seals is very distinct from that of the *phocidae*. Dr. T. Gill, in his "Monograph of the Pinnipeds" (1856), first introduced some order into the confused nomenclature and characters of these seals; and after him J. A. Allen, in the "Bulletin of the Museum of Comparative Zoölogy" (vol. ii., No. 1, 1870), gave special attention to the family. Mr. Allen divides them into *trichophocinae* or hair seals, with the genera *otaria*, *eumetopias*, and *zalophus*, and *oulophocinae* or fur seals, with the genera *arctocephalus* and *callorhinus*. In the *otariadae*, which includes the sea lions and sea bears, the incisors are $\frac{2}{2}$, the four upper middle ones with broad crown divided by a transverse groove, the outer two conical; molars $\frac{2}{2}$ — $\frac{2}{2}$, sometimes with one less above; the fore feet are further back than in the other seals; the hind feet have the membrane prolonged beyond the nails into long straps or ribbons; the fore feet are nailless, and the lower surface of all the limbs is without hair; there are also small external ears, from which these seals are called otaries. The name of sea lion has been given to a number of large seals of both hemispheres, either from their savage appearance, roaring voice, powerful canines, or maned neck. The northern or Steller's sea lion (*eumetopias Stelleri*, Peters) is about 15 ft. long, with a weight of about 1,600 lbs.; the males have stiff curled hair on the neck, a

Southern Sea Lion (*Otaria jubata*).

thick hide, coarse tawny reddish hair, and a mane of erect hair; the head is large, the nose long and truncated, the eyebrows bushy, and

the ears distinct. They are found on the E. shores of Kamtchatka, about the Kurile islands, and the N. W. coast of America, on rugged shores and desert rocks in the ocean; their food consists of fish, the smaller seals, sea otters, and marine birds and animals. The southern sea lion (*O. jubata*, De Blainv.) is of about the same size and general appearance as the last, with similar habits, is heavy and clumsy in its gait, and fears man; it is found in the south seas, sometimes coming to the Patagonian coasts; it is rarely hunted except by savages, though the oil is excellent. The name of sea bear has been applied to many smaller seals of both hemispheres, with a less ferocious aspect but fiercer disposition than the sea lions. The northern ursine seal or sea bear (*Callorhinus ursinus*, Gray) is about the size of a large bear, between 7 and 8 ft. in length; the forehead is much arched, the lips tumid, and the ears nearly 2 in. high; close to the skin is a soft reddish

Sea Bear (*Callorhinus ursinus*).

wool, over which is a dark coarse hair; the females and young are ashy. It is very fat in spring before the young are born; it is polygamous, the males tender to the young but tyrannical to the females; if wounded, it will attack a boat, and is very tenacious of life; it is the terror of the smaller seals and sea otters, and is itself afraid of the sea lion. This species furnishes the greater portion of the fur seal skins of commerce. It is found chiefly on the Pribyloff islands in Behring sea, a group belonging to Alaska, collecting especially on St. Paul's and St. George's islands. The "rookeries" contain several millions of seals; the adult males begin to arrive about the first of May (the great body about the first of June) and the females about the middle of June, giving birth to their young soon after landing; the "bachelor" seals, as males under six years old are called, do not collect on the "rookeries," but have separate "hauling

grounds;" nearly all leave the islands about the end of October or middle of November. The males on the "rookeries" do not go into the water from the time of "hauling up" in May till after the first of August, being sustained in the mean time by the absorption of their own fat. After leaving the islands in autumn, the seals spread out over the North Pacific, following schools of fish, or frequenting shoals and banks where cod are abundant; at this time they are shy and difficult to approach, unless asleep, in which condition they are captured by the natives all along the N. W. coast from the Columbia river to Behring sea; in spring they return to the breeding grounds on the islands. The capture of the seals for their fur begins with their first landing on the islands, and may continue till they begin shedding their fur in August or September; they are killed by the natives with clubs; only the "bachelor" seals are allowed to be captured. The blubber of the fur seal is of a faint yellowish white, and lies entirely between the skin and flesh; it possesses an odor exceedingly offensive, and difficult to wash from the hands. The flesh, when carefully cleaned of fat, can be eaten; it resembles poor, tough, overdone beef. (See *Fur*, vol. vii., pp. 536 and 538.) The southern sea bear (*arctocephalus Falklandicus*, Gray) is smaller than the last, to which it is similar in habits, but larger than the common seal, the males being about 7 ft. long, and the females considerably smaller; the hair is of different colors, black, brownish, gray, and variously spotted with grayish and yellowish, and the under fur is short and fine. It was formerly very abundant about the islands of the southern ocean, especially the Falkland, but is now almost extirpated. Some thousands of skins have recently been obtained, however, at the South Shetland islands by vessels from New London, and there is a small rookery on the Lobos islands protected by the Argentine government. It was from this species that the market was formerly supplied.—A few fossil remains of species nearly allied to the common and monk seals have been found in the upper tertiary formations of Europe and North America, and recently in the Yorktown (miocene) strata of the Atlantic coast, with those of the whale, dolphin, and walrus.—See "The Seal and Herring Fisheries of Newfoundland," by Michael Carroll (Montreal, 1873), and "The Marine Mammals of the Northwestern Coast of North America," by Charles M. Scammon (4to, New York, 1874).

SEAL (Lat. *sigillum*), a piece of metal, stone, or other hard substance on which is engraved some image or device, and sometimes a legend or inscription. It is used for making impressions on wax or like material affixed to legal instruments, as evidence of their authenticity. The word seal sometimes means only the implement employed, but both in legal and in common language it is applied also to the thing impressed. The Bible contains frequent allusions

to seals, and they abound among Assyrian and Babylonian remains. From the East the use of seals passed to Greece and thence to Rome; and it has been common in all the European states from the earliest periods. Among both the Greeks and the Romans the seal was usually set in a ring, whence *annulus* came to be a Latin name for a seal. The word *bullæ* has always been used in Europe to designate specifically an impression in metal, and thus came to be the distinctive appellation of a class of instruments sealed in that way. Such, for example, are the edicts and briefs of the Roman pontiffs (see *BULL*, *PAPAL*), and some constitutions of the German emperors.—The circular form is common to all periods. The ogive, the spade form of the escutcheon in heraldry, appeared with the pointed style in architecture, and in the course of time was exclusively appropriated by abbeys, chapters, bishops, and other ecclesiastical bodies and persons. The oval form was particularly frequent in France during the reigns of the Merovingian and Carolingian kings. The size varied at different periods, and in general the smaller and thicker the seal, the older it is. Those of the Merovingian kings are hardly more than an inch in diameter, while that of Francis I. of France had a breadth of four inches. The Egyptian priests used in sealing a sort of clay. The Byzantine emperors sealed in the form of *bullæ* with lead, and sometimes with silver and gold. Silver *bullæ* are much rarer than those of gold. The wax most anciently employed was white. When, about the 9th or 10th century, wax was made of various colors, only emperors and kings might seal in red. In the 12th century it was customary in France to seal with green wax letters addressed to persons of high eminence. This color was introduced into Germany in the 14th century, and was appropriated by religious houses and cities. Blue seals are very rare, and Charles V. of Germany is said to be the only European monarch who used this color. The patriarchs of Jerusalem and Constantinople, and the grand masters of the order of Malta and of the Teutonic order in Germany, sealed in black. Private persons commonly used yellow wax, and this color is frequent in public documents of about the 12th century.—The devices upon seals throw not a little light upon the manners and usages of different ages, and some of them have positive historical value. The seals of the Romans were engraved with the portraits of their ancestors or friends, with mythological subjects, or with symbolical allusions to the real or mythical history of their families. Perhaps the earliest authentic instance of a seal bearing armorial devices is that of Arnulphus, count of Flanders (941). Such seals were not common until the 13th century. The early seals of religious communities and of cities were inscribed with the image of their patron saint or of some sacred relic, or with the figures of ecclesiastical dignitaries or ma-

gistrates. The name of the owner in seals attached to public documents usually forms part of the inscription. The ancient intaglios were frequently used for seals in the times of the early French kings. They were used chiefly for counter-seals, and by the addition of a pious text or legend it was attempted to give a sacred character to their profane subjects. The most ancient mode of sealing was probably that of applying the wax directly to the parchment. When the instrument was written upon two or more leaves, the wax was made to reach them all by impressing it upon an incision made in the parchment in the form of a cross. The seal was sometimes also made upon the ends of thongs or strips of parchment run through the several sheets. Lead, silver, or gold *bullæ* were almost of necessity appended by a cord or strip. In the 12th century it seems that in France at least pendent seals had displaced the other sort. They are still used generally for letters patent, treaties, and other important public documents. During the 12th century, too, though the practice was not well established until the 13th, arose the contrivance of counter-seals, that is to say, the use of a different impression upon the reverse of the proper seal. They are said to have been first applied to the pendent seals. They were in these cases made of the same size with the chief seals, and the mottoes interrupted on these were continued on the counter-seals.—Although in some periods seals have taken the place of signatures, yet very often seal and signature have been employed together. In Rome, the prætorian law had recognized the validity of testaments that were only sealed by the witnesses; yet an imperial constitution afterward required the adscription of their names also. In the constitutions of the Merovingian and Carolingian kings, the seal ordinarily supports the monogram or signature of the sovereign, but sometimes it stands alone. From the 8th to the 10th century the use of seals in France was confined almost entirely to the kings. Most instruments of this period are attested, so far as the witnesses at least are concerned, only by the mention of their names. About the 12th or 13th century the use of seals among all classes became general, and continued so until the revival of learning and the diffusion of correct writing rendered seals of less use. In England charters and grants of the Anglo-Saxon and Anglo-Danish reigns were authenticated by the signature of the grantor preceded by the figure of a cross. The execution was attested by the subscription of the names of the witnesses, each name being preceded by a cross. Seals were certainly not often used in England until late in the 11th century, and then by no means commonly. There are extant unquestioned seals of Edward the Confessor, and he certainly first adopted a great seal for England; but their general use for authenticating charters and other instruments was not fairly estab-

lished till near the middle of the 13th century. In Scotland, a statute of the time of Robert III. (1390-1406) declared that every baron or tenant *in capite* of the king must have a peculiar seal for his sovereign's service; and a statute apparently in aid of this one, passed in the next reign (James I.), enacts that every freeholder shall appear at the lord's court with his seals, or if he cannot appear in person, he shall send them by his attorney; and it seems to have been customary for gentlemen at this time to deposit copies of their seals in the office of the court of their county, the seal then sufficing without signature to authenticate an instrument. In 1540 a statute of James V. declared that, inasmuch as seals might be lost or counterfeited, all documents must henceforth be not only sealed but subscribed.—From the universal use of seals in England it came to be English law that no charter, grant, or other instrument of conveyance was *factum*, that is, done, or in other phrase a deed, until it was sealed; and such was the virtue of a seal that down to the time of Charles II. it alone sufficed to make a writing valid and binding. The statute 29 Charles II., the so-called statute of frauds, enacted that certain writings should for the future be signed; but it is probably the better opinion that, even since the statute, a deed duly sealed is good without the subscription of a name.—The old common law definition of a seal is that given by Lord Coke: *Sigillum est cera impressa*—"A seal is an impression in wax;" but it has long been held that a wafer or other tenacious substance, on which an impression is or may be made, is a good seal. In many, perhaps indeed most of the United States, neither wax, wafer, nor any other substance is required; a scroll or ring made with the pen in imitation of the seal, or as marking its place, being sufficient. One piece of wax suffices for several signers if stamped with their separate impressions, or several signers may adopt one seal; and an adoption of this sort is inferred when the deed recites the sealing "with our seals," and those who did not in fact seal do yet sign and deliver the deed. The significance of the seal in law at present is, that it imports a deliberate and considered act on the part of him who affixes it. The rule has established itself firmly in the law, that an instrument thus executed with a seal implies a consideration, or in other words that full assent which is essential to the validity of every contract, and which can be inferred only from a seal, or from something of value passing between the parties as the cause of the contract.

SEALSFIELD, Charles, a German author, whose real name was KARL POSTEL, born at Poppitz, Moravia, March 3, 1793, died near Solothurn, Switzerland, May 26, 1864. He became secre-

tary of a religious order at Prague, but escaped from his convent about 1822, and in 1832 settled in a farm house at Solothurn, both before and after which time he resided much in the United States, and visited Mexico and Central America. His principal works are: "Tokeah, or the White Rose" (2 vols., Philadelphia, 1828; in German under the title *Der Legitime und der Republikaner*, 3 vols., Zürich, 1833); *Transatlantische Reiseskizzen* (2 vols., 1833); *Der Virey und die Aristokraten*, a Mexican novel (2 vols., 1834); *Lebensbilder aus beiden Hemisphären* (2 vols., 1834; 2d ed., entitled *Morton, oder die grosse Tour*, 1846); and *Süden und Norden* (3 vols., 1842-'3). These and others of his works have been translated into English, and several of them into French. Two complete editions have been published at Stuttgart (15 vols., 1845-'7, and 18 vols., 1846).—See *Erinnerungen an Sealsfield*, by Kertbény (Brussels and Leipsic, 1864). A monument to him was erected in 1875 in his native place.

SEAMAN, a sailor. Seamen may be hired in four ways. 1. They may be employed for a certain voyage and receive a certain proportion of the freight earned. This contract is probably rarely made in this country, except for small coasting vessels. 2. They may be hired for a certain voyage or by the run, and paid a round sum at the close, and this is not very unusual. 3. They may be hired on shares, which is a practice nearly if not quite confined to whaling and fishing vessels. 4. But much the most common usage is to hire them for some definite voyage or voyages, or for a definite period, on monthly wages. Under penalty of a considerable forfeiture, the United States laws require that every master of a vessel bound from a port in the United States to any foreign port, or of any ship or vessel of the burden of 75 tons or upward bound from an Atlantic to a Pacific port or *vice versa*, shall have shipping articles, which must be signed by every seaman on board, and must describe accurately the voyage and the terms upon which the seaman ships. Articles which are less particular are required in case of vessels of 50 tons and upward bound from a port in one state to a port in any other than an adjoining state. Wherever there is doubt as to the meaning of the obligation, the sailor, rather than the ship owner, has the benefit of the doubt. The shipping articles ought therefore to declare explicitly the ports of the beginning and end of the voyage, and in all other respects ought to be clear and fair. To all clauses or stipulations which tend to lessen the usual rights of the seaman, it must appear that he gave intelligent and deliberate assent. Accidental omissions in the articles may be supplied by parol; and a seaman may also by parol show that the voyage or time represented to him was not that which appears in the papers, or that the articles have been altered since they were subscribed. The owner is bound to

provide a seaworthy ship, and our statutes furnish the means of lawfully ascertaining her condition on the complaint of one of the mates and a majority of the crew, by a regular survey at home or abroad. If seamen, after shipping, refuse to proceed on the voyage and are arrested for the mutiny, the condition of the vessel, if that is the excuse, is inquired into by the court; and if she is found unseaworthy, their punishment is reduced and mitigated accordingly. So, unseaworthiness is a sufficient defence to the charge of endeavoring to commit a revolt by compelling the master to return to port. Provisions of due quality and quantity are to be furnished by the owner, under the general principles of law as applied from the earliest times to this particular contract. The quantity for each man on board is here prescribed by statute, under penalty of a day's wages to every seaman for the days on which he is on short allowance. But these wages are not to be paid if the necessity of short allowance arose from a peril of the sea or any accident of the voyage, or the delivery of a part of the provisions to another vessel in distress. Nor, as it is clear that the master must have a discretion in the expenditure of the provisions, is putting the crew on an allowance necessarily the same thing as putting them on short allowance. A deficiency in one kind of provisions is not compensated by an abundance of another. By the general law merchant there is an obligation upon every ship owner or master to provide for a seaman who becomes sick, wounded, or maimed in the discharge of his duty, whether at home or abroad, at sea or on land, if it be not by his own fault, suitable care, medicine, and medical treatment, including nursing, diet, and lodging. Sickness is provided for by express statutes, which go so far as to require that every ship bound from a port of the United States to any foreign port, or being of the burden of 75 tons and upward and bound from an Atlantic to a Pacific port or *vice versa*, should have a proper medicine chest on board. Whenever other appliances are required, or whenever surgical skill, or attendance, or nursing, other and better than that which the ship can afford, becomes necessary, the expense will be charged on the owners under the general maritime law. By other statutes the master may deduct 40 cents a month from every seaman's wages to make up a fund for the support of marine hospitals, in which every sailor may have medical treatment.—Disobedience or misconduct of a sailor is of necessity punishable with great severity. Formerly there was no specific limit to the right of punishment; it might be administered by the master in any form and in any measure, he always being responsible for any excess or cruelty, both criminally and in damages to the seaman. But by the statute of 1850 flogging is abolished and prohibited. This has been declared by very high authority to include the

use of the cat and every similar form of punishment, but not necessarily to include all corporal punishment, such as a blow with the hand, or a stick or rope. The statute contemplates deliberate flogging, and not that sudden violence, like blows, which may be inflicted in an emergency, to compel immediate obedience. Generally the only punishments which can now be resorted to, to secure good conduct, are forfeiture of wages, irons, imprisonment, hard labor, and such other means as may be invented in the place of flogging. The penalty of forfeiture of wages may not be imposed for one trivial act of irregularity, nor for a single or occasional act of intemperance; the offence must be habitual to warrant the infliction of the penalty. The master or a seaman may forfeit all his wages for smuggling; or the damage actually sustained by the owners of the vessel from this offence may be charged upon the wages of the offender, but only those wages earned before the act of misconduct are forfeitable.—Desertion is distinguished from absence without leave by the intention not to return. Thus, it is not desertion for the seaman to leave the ship, against orders, for the purpose of entering complaints for ill treatment before the consul; nor is it desertion when the vessel is left for a good cause, as a change of the voyage without consent, cruelty, insufficient provisions, or unseaworthiness of the ship. The seaman must be received, if he offers to return in a proper way and in a reasonable time, before any other person is engaged to take the place. If he returns after desertion and is received by the master, or by the owner, this is a condonation of his offence and a waiver of the forfeiture, and it has this effect even if there be a clause to the contrary in the shipping articles. If the sailor deserts before the voyage begins, by not rendering himself on board, he forfeits his advance wages and an equal sum in addition, or he may be apprehended under the warrant of a justice and be compelled to go on board. If he deserts on the voyage, he forfeits all or any part of his wages and all or any part of his property on board the ship.—The right of the sailor to be brought back to his home is very jealously guarded by our laws. Every ship must be provided with the shipping articles and a shipping list verified under the oath of the master; this he is required to present to the consul or commercial agent of the United States at every port which he visits, when so requested, and is under bond to deliver to the boarding officer who comes on board his ship at the first home port which he reaches, and to produce the persons named therein that it may be ascertained that he has his whole crew on board. If it appears that any of them are missing, he must account for their absence. If he discharges any of them abroad, with his or their own consent, he must pay to the American consul of the port or the commercial agent, over and

above the wages then due, three months' wages, of which two thirds are paid to the seaman, and one third retained by the consul and remitted to the treasury of the United States, to form a fund for the maintenance of American seamen abroad and for bringing them home. If repairs to the ship become necessary, or if the ship is captured, the seamen may hold on for a reasonable time awaiting the prosecution of the voyage; and if discharged before this time has elapsed, they may claim their extra wages. The discharge of a seaman for good cause, like disobedience, misconduct, or disability by his own fault of extreme degree, may be authorized by our consuls or commercial agents in foreign ports. If the ship is unseaworthy, the shipping articles are violated by the master, or the sailor is subjected to cruel treatment, he may be discharged by a consul and recover his three months' pay. If the master discharges the seaman, against his consent and without good cause, in a foreign port, he is liable to a fine of \$500 or six months' imprisonment, and the seaman may recover full indemnity for all loss or expense incurred by such discharge.—It is an ancient maxim of the maritime law that freight is the mother of wages, so that where no freight is earned no wages are earned. But, more properly speaking, wages are earned whenever freight is or might be earned, for the sailor ought not to and does not lose his dues when the ship fails to earn freight on account of the fraud or wrongful act of the master or owner. Nor will any special contract between the owner and the freighter, varying the obligation to pay freight from that implied by the general law, have any effect upon wages. If the voyage is broken up, or the seamen are dismissed without cause before the voyage begins, they have their wages for the time they serve, and a reasonable compensation for special damages. In cases where the voyage is broken up by misfortune, so that the master would be justified in discharging the crew, they are still entitled to their wages. So a seaman has full wages if he is compelled to desert by the cruelty of the master, or if he is disabled by sickness, even if, by reason of that sickness, he was obliged to be left at a foreign port. Seamen have a lien for their wages on the ship and freight. Statutes give the same lien to fishermen on shore. It attaches not only to ship and freight *in re*, but to the proceeds of both or either, and follows them into whose hands soever they may go. It prevails over bonds of bottomry and other like hypothecations, because the services of the sailor save the ship for all claimants. Pilots, engineers, firemen, and deck hands are seamen, and have this lien, and so have all persons whose service is materially and directly useful to the navigation of the vessel. A seaman cannot insure his wages, nor derive any benefit from the insurance effected by owners on ship or freight. It is the policy of the law, for obvious rea-

sons, to make the sailor find all his interest in the security and welfare of the ship.

SEA MOSSES. See POLYZOA.

SEA NETTLE. See ACALEPHÆ, and JELLY FISH.

SEA PIE. See OYSTER CATCHER.

SEA PORCUPINE, a common name of the osseous fishes of the order *plectognathi* (with comb-like gills), family *diodontidæ* or gymnodonts, and genera *diodon*, *tetraodon*, &c., so called from the spines with which the body is studded. This order, which contains the sun fish, trunk fish (see TRUNK FISH), and file fish, has the internal skeleton partly ossified, and the skin covered with ganoid scales or spines; the maxillaries and intermaxillaries are wholly or in part united, and the upper jaw in most is immovably fixed to the cranium; there are no pancreatic cæca, no well developed ventrals, no duct to the air bladder, and only vestiges of ribs. In the family of gymnodonts the teeth are incorporated with the bone of the jaws, and resemble a parrot's beak with or without mesial division, their plates consisting of hard dentine adapted for bruising and cutting the crustaceans, mollusks, and sea weeds upon which they feed. The skin is thick, leathery, and armed with spines which stand out in every direction when the body is inflated by filling with air the stomach, or more properly a large sac beneath this organ communicating with the œsophagus; the air is forced into this sac by swallowing; when thus distended the fish loses all command over its fins, and rolls over belly upward, floating at the mercy of the wind and waves; as it is a considerable time before the air can be sufficiently expelled to allow the fish to resume the full control of its movements, many are caught in this helpless condition; they emit a blowing sound when taken, from the expulsion of the air; the tail is short and feeble; the spinal cord, according to Owen, is very short. Some of the family have no external openings to the nostrils, the nerve of smell being expanded on cutaneous tentacles. The flesh of some is poisonous. They are very tenacious of life, on account of the small size of the gill openings, and have a disagreeable odor which is retained even in alcohol for years; they are mostly inhabitants of tropical seas, and are rarely more than 2 ft. in length, with the diameter of the inflated body more than half of this.—In the genus *diodon* (Linn.) there is no mesial division of the jaws, and the teeth are apparently only two; the spines are long, thin, sharp, with two root-like processes, and capable of erection. There are nine species, of which three are described by Mitchill as occurring on the coasts of the United States, under the name of balloon fishes; these are the *D. maculo-striatus*, about 6 in. long, greenish spotted and striped with dark; the *D. pilosus*, smaller, with most of the body furnished with soft, flexible bristles of a golden color; and the *D. verrucosus*, with a warty and spiny skin. The atinga (*D. hystrix*, Bloch), of the East In-

dian, S. African, and South American coasts, is the best known to seamen; it is caught in nets or on hooks, and is very difficult to handle from the sudden erection of the spines

Balloon Fish (*Diodon pilosus*).

and the active motions of the body.—In *Tetraodon* (Linn.) there is a mesial suture in the jaws, so that there appear to be two teeth above and two below; the spines are very short, and the head, back, and tail are generally smooth. The *T. electricus* (Paterson), with electric properties, has the skin entirely smooth. (See ELECTRIC FISHES.) There are several species on the American coast, of which the most common is *T. turgidus* (Mitch.), 6 to 14 in. long, olive-green above and whitish below; the abdomen lax, covered with prickles

Puffer or Swell Fish (*Tetraodon turgidus*).

and capable of considerable distention; it is not uncommon about Martha's Vineyard, and on the Massachusetts and New York coasts, where it goes by the names of puffer and swell fish. Other names for this and the preceding genus are globe fish, urchin fish, and spine-belly.

SEA RAVEN, an acanthopterous fish of the bullhead or sculpin family, and genus *hemitripterus* (Cuv.), one of the ugliest of this ugly group. The head is flattened, rough, and spiny; the pectorals are large and wing-like, advancing far under the throat, and with no free rays; ventrals under the pectorals, consisting of a spine and three or four soft rays;

the first dorsal deeply notched, and all the fin rays simple; the head and jaws are furnished with numerous cutaneous branching filaments, which with the spines and huge mouth render the physiognomy of the fish anything but pleasing; there are sharp, card-like teeth on the jaws, vomer, palate, and pharyngeal bones; the tongue is smooth, the branchiostegal rays six, and the body without scales. The typical species is the common sea raven (*H. Acadianus*, Storer), called also the Acadian bullhead and deep-water sculpin; it attains a length of 2 ft. and a weight of 4 or 5 lbs. The colors present every shade of dark brown, blood red, pinkish purple, and yellowish brown, with various markings and bands; yellowish white below. The form is sculpin-like; the head is large, about a quarter of the whole length, with enormous gape and hideous appearance; the whole body above the lateral line is granulated, and thickly studded with tubercles; the first three rays of the first dorsal are longest, and with the other rays of this fin are fringed at the end. It is not unfrequently taken on

Common Sea Raven (*Hemitripterus Acadianus*).

hooks by cod fishermen in deep water in Nova Scotia, in the gulf of St. Lawrence, and near the New England and New York coasts, especially around the ledges of Massachusetts bay. Like the land raven, it is omnivorous and voracious, acting the part of a useful scavenger in removing decaying matters.

SEARCH, Right of, the right of a belligerent to visit, by his lawfully commissioned cruisers, all private ships sailing on the high seas, and to examine their papers, and their cargoes if need be, in order to ascertain their destination and character. It is a familiar doctrine of international law that the ships of a state form a part of its domain, and that over them, as over its landed territory, the sovereignty of the state extends supreme and inviolable. In a time of general peace, these ships cannot be detained or boarded by the public ships of another power for the purpose of inquiry into their character or business, because such an act is an intrusion upon and in derogation of the sovereignty of the state whose ships are so visited. In time of war, however, the general consent of nations yields to the belligerents the privilege of visiting and searching ships professing to be neutral, in order that they may know that the neutral flag does not mask

an enemy or cover contraband of war. So firmly is this rule or right established that there is no doubt or dispute about it among institutional writers, and it has never been successfully resisted in the practice of nations. During the American revolutionary war, and in 1801, the Baltic powers declared that the flag of a state was a substitute for all documentary proof, and excluded the right of search. They armed themselves for the purpose of defending and maintaining this position, but they were soon compelled to abandon it, and since that time the usual war right has been considered incontrovertible. The question was once submitted in the English admiralty whether neutrals might not compel a belligerent to refrain from exercising his right by putting their ships under the convoy of a public ship of their country. It was adjudged that the belligerent was not bound to accept such a substitution, nor indeed in any respect to vary his right of personal visitation. It may be remarked in passing that two powers sometimes regulate or restrain by treaty the right of maritime search by ships of war. The English doctrines upon the war right of search have been generally admitted in this country, except as to the claim put forth by England of a right to search neutral vessels on the high seas for deserters and other persons liable to military and naval service. The difference upon this point was one of the chief causes of the war of 1812, and the matter has never yet been specifically settled, but it cannot be supposed that the British claim will ever be reasserted. Recent modifications of belligerent rights have not materially limited or affected the right.

SEARCY, a N. county of Arkansas, intersected by the Buffalo fork of White river; area in 1870, about 950 sq. m., subsequently reduced by a portion taken to form Stone county; pop. in 1870, 5,614, of whom 30 were colored. The surface is hilly and the soil productive. Extensive forests cover a large portion of the county. The chief productions in 1870 were 21,961 bushels of wheat, 263,812 of Indian corn, 11,852 of oats, 25,008 lbs. of tobacco, 4,389 of wool, and 2,180 bales of cotton. There were 1,512 horses, 200 mules and asses, 1,619 milch cows, 2,886 other cattle, 2,711 sheep, and 15,682 swine. Capital, Marshall.

SEA ROBIN. See GURNARD.

SEARS, Barnas, an American clergyman, born in Sandisfield, Mass., Nov. 19, 1802. He graduated at Brown university in 1825, studied theology at Newton, Mass., was pastor of the first Baptist church in Hartford, Conn., for two years, and in 1829 became a professor in the Hamilton literary and theological institution, now Madison university, New York. In 1833 he went to Germany to study, and on his return was appointed to a professorship in the theological seminary at Newton, and for several years was its president. In 1848 he was made secretary and executive agent of the Massachusetts board of education. In

August, 1855, he was elected president of Brown university, which office he held till February, 1867, when he became general agent of the Peabody education fund. He received the degree of D. D. from Harvard university in 1841, and LL. D. from Yale college in 1862. Dr. Sears has published "Ciceroniana, or the Prussian Mode of Instruction in Latin" (1844); "Select Treatises of Martin Luther in the Original German" (1846), with philological notes; "Life of Luther, with special reference to its earlier Periods and the Opening Scenes of the Reformation" (1850); and a revised edition of Roget's "Thesaurus" (1854). He edited the "Christian Review" for several years.

SEARS, Edmund Hamilton, an American clergyman, born in Sandisfield, Mass., in 1810. He graduated at Union college in 1834, and at the Harvard divinity school in 1837. In 1839-'40 he was pastor of the first Unitarian church in Wayland, Mass., and in 1840-'47 in Lancaster, Mass. In conjunction with the Rev. Rufus Ellis, he edited for several years the "Monthly Religious Magazine," Boston; and in 1865 he became pastor of the Unitarian church in Weston, Mass. He has published "Regeneration" (Boston, 1853; 9th ed., 1873); "Pictures of the Olden Time" (1857); "Athanasia" (1857; 11th ed., enlarged, 1873, with the title "Foregleams and Foresplendors of Immortality"); "The Fourth Gospel the Heart of Christ" (1872); and "Sermons and Songs of the Christian Life" (1875). He received the degree of D. D. from Union college in 1871.

SEA SERPENT, a marine animal, by many considered fabulous, said to inhabit chiefly the northern seas, especially about the coasts of Norway and New England. The idea of a sea serpent originated in northern Europe, and was at first clearly mythological. Though hundreds of witnesses aver that they have seen this animal, naturalists have failed to discover any certain traces of it. For an account of its visits to Norway the reader may consult Pontoppidan's "Natural History of Norway" (fol., London, 1755), and vol. viii. of the "Naturalist's Library" (Edinburgh, 1841); and for its occurrence on the American coasts, vols. ii., xi., xii., and xxviii. of the "American Journal of Science," the "Report of the Committee of the Linnean Society of New England" (Boston, 1817), Sir Charles Lyell's "Second Visit to the United States" (London, 1849), and Gosse's "Romance of Natural History" (London, 1860-'62). This animal is said to appear in calm weather, with a slender body from 60 to 100 ft. long, a broad snake-like head as large as that of a horse, large eyes, and a long and narrow neck, and of a general dark brown color; some describe it as having fins. It is seen swimming at the surface, with the head and neck elevated, progressing swiftly, apparently by a vertical undulating motion. There does not seem to be any fish to which this animal can be referred. Many fossil types of marine animals have been transmitted, with

or without interruption, from remote geological epochs to the present time; among these may be mentioned the Port Jackson shark (*cestracion*), and the gar pike (*lepidosteus*), which have come down to us without interruption, *chimara*, *percopsis* of Lake Superior, and soft-shelled tortoises (*trionychidae*), with more or less apparent disappearance. Several years ago it was suggested that the closest affinities of the sea serpent are with the marine lizards or enaliosaurians of the secondary age, and especially with the plesiosaurus. (See PLESIOSAURUS.) On the above principle it is maintained that the enaliosaurians, found in the secondary, may have disappeared, actually or apparently, in the tertiary, to reappear at the present time. This is also the opinion of Agassiz, as given in the report of his lectures in Philadelphia in 1849, and reaffirmed in his "Geological Researches" (1871). Mr. Gosse has collected from various sources the arguments showing that the non-occurrence of dead animals is of little weight as disproving the existence of the sea serpent; its carcass would float only a short time, and the rock-bound coasts of Norway would be very unlikely to retain any fragment cast up by the waves; many whales are known to naturalists only from two or three specimens in as many centuries. The zeuglodon, a mammalian type of the tertiary epoch, coming near to the cetaceans and in some respects to the seals, may present some claim to be the sea serpent. (See ZEUGLODON.) The conclusion of the best naturalists is that the existence of the sea serpent is possibly a verity, and that it may prove to be some modified type of the secondary enaliosaurians, or possibly some form intermediate between them and the elongated cetaceans.—See "Proceedings of the Boston Society of Natural History," vol. xvi. (March, 1874).

SEA SICKNESS, an affection attended with nausea and vomiting, produced by the motion of a vessel at sea. Similar symptoms are also produced by swinging, waltzing, and riding backward in a coach; but the greater and more regular oscillations of a ship have a stronger effect upon the nervous system. The susceptibility to this malady varies greatly; some persons never experience nausea from this cause; others may only suffer a few hours during a voyage of several days; while still others are almost constantly sick while aboard ship, and fatal cases have been known. The premonitory symptoms are vertigo and sometimes headache, and a peculiar feeling of "sinking" and distress at the pit of the stomach. Nausea soon appears, attended by distressing and convulsive vomiting and frequently diarrhoea. It is more likely to attack those who are debilitated, or who have suffered nervous exhaustion or excitement consequent upon making preparations for the voyage, especially if there has been imprudence in taking food. Dr. Chapman, who wrote a pamphlet "On Sea

Sickness, its Nature and Treatment" (London, 1864), is of opinion that "the motions of the vessel cause the accumulation of an undue amount of blood in the nervous centres along the back, and especially in those segments of the spinal cord related to the stomach and the muscles concerned in vomiting." The remedy which he asserts is the most scientific and efficacious is the application of ice bags to the spinal column, which act, according to his theory, as a sedative. They are made of thin caoutchouc, and are worn by the patient while walking about in ordinary apparel. Dr. For-dyce Barker, in a pamphlet on sea sickness, advises the observance of the following rules, which are principally preventive. In short passages over rough water, those who are susceptible should make a hearty meal not more than two or three hours before going on board, and should keep as near as possible to the centre of the vessel, and lie down before she gets under way. The person should be well covered and shielded as much as possible from disagreeable sights and smells. For ocean passages similar care as to location should be observed in selecting berths. As a general rule of prevention, Dr. Barker advises regular and hearty eating in bed for one or two days, and during the voyage to take coffee or tea or some drink and food before rising in the morning. There is often a tendency to constipation, which may be overcome by the use of laxatives. During an attack, especially if accompanied by diarrhoea, medicines similar to those used in cholera morbus may be taken, as tincture of camphor, tincture of lavender combined with tincture of opium and tincture of capsicum, or a few drops of chloroform. Stimulating liniments may be applied to the pit of the stomach. If during the voyage the weather becomes rough, it is advisable to go to bed before getting sick.

SEA SNIPE. See BELLOWS FISH, and PIPE FISH.

SEASONS (Fr. *saisons*), the quarters of the year, spring, summer, autumn, and winter. These periods are determined astronomically by the apparent movements of the sun (the real movements of the earth) in the ecliptic. The passage of the sun across the equator, bringing on days of greater length than the nights, marks the vernal or spring equinox, and occurs about March 21 for the northern hemisphere and Sept. 23 for the southern. These dates also mark the autumnal equinox or commencement of the autumn, the hemispheres being reversed. The summer solstice, when the day is of greatest length and the astronomical summer begins in the northern hemisphere, is about June 21, and the winter solstice about Dec. 21. In the figure, S represents the position of the sun, A the position of the earth at the vernal equinox in the northern hemisphere (about March 21), and N the north pole. Both poles just catch the light of the sun, and in all other parts of the

world the days and nights are equal; but at the north pole the sun is just rising, at the south pole he is just setting. B represents the position of the earth at the summer solstice (about June 21). The north pole has been continually exposed to the sun for three months, and it is the noon of the north polar day. The direct light of the sun reaches about $23^{\circ} 28'$ beyond the pole, and consequently anywhere within that distance of the pole the sun is visible during the whole 24 hours. Within the same distance of the south pole it is continual night. (See POLAR CIRCLES.) C is the position of the earth at the autumnal equinox of the northern hemisphere (about Sept. 23), but the sun is just setting at the north pole and just rising at the south, and again everywhere else the days and nights are equal. D is the position of the earth at the winter solstice of the northern hemisphere (about Dec. 21); it is the noon of the south polar day, the midnight of the north polar night. It will be seen that at the poles the day and the year are coincident, if we consider a day as made up of one period during

Positions of the Earth in its Orbit.

which the sun is visible and one during which he is invisible.—The popular divisions of the year do not correspond with those of the astronomer, and are not the same in different countries. In England the spring begins with February, summer with May, autumn with August, and winter with November; but in the United States the seasons begin respectively with the months succeeding those named. The marked changes in the amount of heat and light imparted by the sun in the different seasons upon those portions of the earth outside the tropics are not experienced in the equatorial regions. The sun as it passes twice each year over these regions sends down its rays so directly upon them, that the variations of temperature are comparatively inconsiderable; but the regular winds and rains and dry periods consequent on the movement of the sun in the ecliptic are the most marked periodic phenomena, and by these the year is divided into two dry and two wet seasons.

SEA SPIDER. I. See SPIDER CRAB. II. The common name of certain marine arachnids of the order *podosomata*. They have no respiratory organs, and only four pairs of legs, which

in some forms attain an extraordinary length; they are grotesque-looking, and are found at low water on stones or marine plants, or attached as parasites to other animals.

SEA SQUIRT, a name popularly given to the single ascidians or tunicates, from their power of forcibly ejecting water from their muscular sacs. (See MOLLUSCOIDS.)

Sea Spider (*Pycnogonum littorale*).

SEA SWALLOW. See TERN.

SEATON, William Winston, an American journalist, born in King William co., Va., Jan. 11, 1785, died in Washington, D. C., June 16, 1866. He successively edited the "Petersburg Register," the "North Carolina Journal" at Halifax, and the "Register" at Raleigh, N. C.; and in 1812 became partner with his brother-in-law Joseph Gales, jr., in the "National Intelligencer" at Washington, which, after the death of Mr. Gales in 1860, he continued to edit alone till 1865. From 1812 to 1820 Gales and Seaton were the exclusive reporters as well as editors of their journal, one of them devoting himself to the senate and the other to the house of representatives. Their "Register of Debates" is one of the standard sources of American history. For 12 consecutive years, beginning with 1840, Mr. Seaton was elected mayor of Washington city. (See GALES, JOSEPH.)

SEA UNICORN. See NARWHAL.

SEA URCHIN. See ECHINUS.

SEA WEEDS. See ALGÆ.

SEA WOLF. See WOLF FISH.

SEBASTE. See SAMARIA.

SEBASTIAN, a W. county of Arkansas, bounded W. by the Indian territory and N. by the Arkansas river; area, about 600 sq. m.; pop. in 1870, 12,940, of whom 1,354 were colored. The Poteau hills, a southern offshoot of the Ozark mountains, traverse a part of the county, and are rich in minerals. The soil is well adapted to grazing and the production of grain and cotton. Bituminous coal is abundant. The chief productions in 1870 were 18,518 bushels of wheat, 362,019 of Indian corn, 16,084 of oats, 25,453 of sweet and 13,703 of Irish potatoes, 2,215 bales of cotton, 28,289 lbs. of tobacco, 3,494 of wool, 142,347 of butter, 11,675 gallons of sorghum molasses, and 1,099 tons of hay. There were 3,060 horses, 670 mules and asses, 4,284 milch cows, 1,040 working oxen, 5,437 other cattle, 2,788 sheep, and 35,848 swine. Capital, Greenwood.

SEBASTIAN, Dom, king of Portugal, born in Lisbon, Jan. 20, 1554, killed in battle in Africa, Aug. 4, 1578. He succeeded his grandfather John III. in 1557, and in his 21st year undertook with 800 or 900 soldiers an expedition against Tangier, the result of which encouraged him to still greater effort. The war raging in Morocco between Muley-Malek and his nephew Muley-Mohammed, the latter of

whom had been deprived of the throne by the former, seemed to offer a favorable opportunity for the Portuguese monarch to interfere. With a large fleet, having on board 15,000 or 20,000 soldiers, he sailed to Africa to support the cause of the nephew in 1578. He found Muley-Mohammed at Tangier, but the landing of his forces took place at Azila, where he was joined by Muley-Mohammed with his forces, and together they began the campaign by the siege of Alcazar. Muley-Malek, who had collected an immense army, gave battle, Aug. 4. After a desperate engagement, in which Sebastian displayed great heroism but no generalship, his army was routed and almost all killed or taken prisoners; and he himself disappeared, but his dead body is said to have been recognized on the field by a page. Muley-Mohammed was drowned in the flight, and Muley-Malek, who had risen from his sick bed to participate in the action, died, so that all the chiefs perished. The flower of the Portuguese nobility was destroyed in this expedition, and Portugal, becoming a prey to anarchy, soon fell into the power of Spain. But the Portuguese could not believe that their king had been killed, and many adventurers sprung up who gave themselves out as the true Sebastian. Among these impostors the most remarkable was one who appeared in Venice 20 years after the battle, and asserted that he was left upon the field among the dead and wounded; that he had remained in Barbary, finally took the resolution of disclosing himself to the pope, on the way was plundered by robbers, and was recognized by a few Portuguese and taken to Venice. The senate of that city banished him, and on his return imprisoned him; but his case excited universal sympathy in Europe, and he was finally set at liberty. He was imprisoned again at Florence, then taken to Naples, and, insisting upon his statements, was treated as a galley slave. He is said to have died in prison in Castile.—See *Le faux Don Sébastien*, by D'Antas (Paris, 1865).

SEBASTIAN, Saint, a Roman martyr, born at Narbonne in Gaul about 255, died in Rome, Jan. 20, 288. According to the "Acts of St. Sebastian," written before 403 and attributed to St. Ambrose, he was educated in Milan, became a captain of the prætorian guard, and distinguished himself by his zeal in spreading the Christian faith. Being summoned for this before the emperor Diocletian, he refused to abjure Christ, and was shot with arrows and left for dead, but was found still alive by a Christian woman, through whose care he was restored. Having ventured to appear before Diocletian to remonstrate against his cruelty, he was beaten to death with clubs and his body thrown into a sewer, but afterward recovered. A church was built over his tomb by Pope Damasus (366-384); and his remains, according to some writers, were given to the abbot of St. Denis, near Paris, by Pope Eugenius II. (824-827), but were deposited at St.

Medard in Soissons. Portions of his relics were distributed throughout Christendom. He became one of the most popular saints of the middle ages, innumerable churches were named after him, and the acts of his martyrdom were a favorite theme for artists. He is generally represented as tied to a tree and pierced with arrows. His feast is celebrated on Jan. 20 in the Latin church, and on Dec. 20 by the Greeks.

SÉBASTIANI, François Horace Bastien, count, a French soldier, born near Bastia, Corsica, Nov. 11, 1775, died in Paris, July 21, 1851. After several years' service, he became prominent in the Italian campaigns of Bonaparte, whom he aided in the *coup d'état* of the 18th Brumaire, and who after the battle of Austerlitz (1805) appointed him general of division. In 1802 he visited Constantinople to alienate Selim III. from Russia and England. In 1806 he went there again as ambassador, and thwarted English intervention; but the success of his mission was frustrated by the sultan's deposition. Subsequently he joined the army in Spain, from which he withdrew in May, 1810, after incurring Napoleon's displeasure by boasting too much of his exploits. In the Russian campaign of 1812, and in the battles of 1813 and 1814, he displayed great valor. On the first abdication of the emperor he joined the Bourbons, but went over to Napoleon after his return from Elba. In 1819 he was elected to the chamber of deputies, of which he remained a member for many years. Under Louis Philippe he became minister of marine in August, 1830, and of foreign affairs in November. His blind devotion to the king's peace policy led to his retirement in October, 1832, but in the following March he reëntered the cabinet as minister without a portfolio. He finally withdrew, April 1, 1834, on the rejection by the chamber of his provisional indemnity treaty with the United States. He was ambassador to Naples in 1834-'5, and to London in 1835-'40, after which he was made a marshal. In 1847 his only daughter was murdered by her husband, the duke de Praslin.

SEBASTOPOL, or *Sevastopol*, a fortified city of Russia, in the Crimea, on a peninsula on the S. side of the roadstead of the same name, an arm of the Black sea, 190 m. S. E. of Odessa; pop. about 12,000. It has a celebrated harbor $3\frac{1}{2}$ m. long and from 700 yards to 1 m. wide. In 1854-'5 the place was invested by the allied English, French, Sardinian, and Turkish armies, and after a protracted siege was taken, Sept. 8, 1855. (See CRIMEA.) One of the churches was erected by Vladimir I., the first Christian czar, out of the remains of the ancient cities of the Chersonesus. In 1780, when Russia commenced fortifying Sebastopol, it was a small Tartar village named Akhtiar. It became a city remarkable for fine streets, buildings, and quays, and as one of the greatest military harbors in the world; and before the Crimean war it had a population of about 47,000, including many marines and soldiers,

but only 4,500 women. Much of it has since been rebuilt.

SECCHI, Pietro Angelo, an Italian astronomer, born in Reggio in Emilia, July 29, 1818. He became a Jesuit Nov. 3, 1833, studied mathematics under Padre de Vico, and taught physics in the college of Loreto from 1841 to 1843. In 1844 he began his course of theology in the Roman college, completed it at Georgetown college, D. C., in 1848-'9, and taught physics and mathematics there till the autumn of 1850, when he was recalled to Rome. He was then appointed director of the observatory of the Roman college, reconstructed it on a new site and plan, invented and perfected a system of meteorological observation, published a monthly bulletin continued till 1873, and constructed a meteorograph much admired at the Paris exhibition of 1867. He was commissioned by Pius IX. to complete the trigonometrical survey of the Papal States begun by Boscovich in 1751, and to rectify the measurements already made of the meridional arc, and executed successfully a commission to bring a supply of water to Rome from Frosinone, 48 m. distant. The results of his labors in every field of astronomical research since 1850 are chronicled in the scientific periodicals of Italy, France, Germany, and England. He is especially distinguished for his discoveries in spectroscopic analysis and in solar and stellar physics. After the closing of the Roman college and the expulsion of the Jesuits (1870-'73) Secchi was allowed to retain his post, continued to lecture on astronomy in the ecclesiastical schools of Rome, and in 1875 he was sent by the Italian government on a scientific mission to Sicily. Among his important publications are: "Researches on Electrical Rheometry," originally in the "Smithsonian Contributions to Knowledge" (Georgetown, 1852); *Quadro fisico del sistema solare secondo le più recenti osservazioni* (Rome, 1859); *Catalogo delle stelle* (Paris, 1867); *Sugli spettri prismatici delle stelle fisse* (Rome, 1868); *Le recenti scoperte astronomiche* (1868); *Nove ricerche sulle protuberanze solari* (1869); *Sur l'influence de l'atmosphère sur les raies du spectre et sur la constitution du soleil* (1869); *Fisica solare: sulle ultime scoperte spettroscopiche fatte nel sole* (1869); "Spectrum Observations on the Rotation of the Sun" (London, 1870); *Le soleil: exposé des principales découvertes modernes sur la structure de cet astre, son influence et ses relations avec les autres corps célestes* (Paris, 1870; German translation by Schellen, Brunswick, 1872); and *Dell' unità delle forze fisiche* (Rome, 1875; French translation, Paris, 1875).

SECKENDORF. I. Veit Ludwig von, a German scholar, born near Erlangen, Dec. 20, 1626, died in Halle, Dec. 18, 1692. In 1642 his father, Joachim Ludwig von Seckendorf, was executed for attempting to desert from the Swedish army, in which he was a colonel, and the son found a patron in Duke Ernest the Pious of Gotha. Shortly before his death the

elector Frederick III. of Brandenburg (the future king Frederick I. of Prussia), to whom he had dedicated his often republished *Fürstenstaat*, appointed him chancellor of the new university of Halle. The most celebrated of his works, *Commentarius Historicus et Apologeticus de Lutheranism* (3 vols., Leipsic, 1688-'92), was written in refutation of Maimbourg's *Histoire du Luthéranisme*. **II. Friedrich Heinrich**, count, a German soldier, nephew of the preceding, born at Königsberg, Franconia, July 5, 1673, died at Meuselwitz, near Altenburg, Nov. 23, 1763. In 1695 he entered the English and Dutch service, but afterward joined the imperial army and fought under Prince Eugene against the Turks and in the war of the Spanish succession. He subsequently became a major general in the army of Augustus II. of Poland and Saxony, and in 1713 was the Polish ambassador to the Hague in the conferences which led to the peace of Utrecht. After the fall of Stralsund in 1715 he reentered the imperial service, in 1719 became count of the empire, and in 1721 *Feldzeugmeister* and governor of Leipsic. Five years later he was sent as ambassador to Berlin by the emperor Charles VI., and in October, 1726, concluded the treaty of Wusterhausen. Subsequently he negotiated the marriage of the future Frederick the Great with the princess Elizabeth, for which the former never forgave him. In the war of the Polish succession he defeated the French at Klausen, Oct. 20, 1735. On the death of Prince Eugene in 1736, he received the command of the army against the Turks. In the campaign of 1737 Seckendorf's intentions were all thwarted by orders from the court of Vienna, and he was recalled and imprisoned for three years in the castle of Gratz. After his release he commanded the troops of the elector Charles Albert of Bavaria (crowned in 1742 as Charles VII. of Germany), with varying success, against Austria, and finally in 1744 recovered Munich for Charles. In April, 1745, he appeared at Füssen in what Carlyle calls "the questionable capacity" of negotiator of a peace with Austria, which caused his reinstatement in his dignities at Vienna, but gave umbrage to Frederick the Great, who had him imprisoned at Magdeburg on some slight pretext, and released after six months on his paying 10,000 thalers.

SECKER, Thomas, an English prelate, born at Sibthorpe, Nottinghamshire, in 1693, died in London, Aug. 3, 1768. He belonged to a family of nonconformists, and studied for the dissenting ministry, but became a physician. Subsequently he was induced to conform, and was ordained in 1723. He was distinguished as a preacher, and became bishop of Bristol in 1735 and of Oxford in 1737, and in 1758 archbishop of Canterbury. His works comprise sermons, lectures, and charges (last ed., with a memoir by Bishop Porteous, 6 vols., London, 1811).

SECOND, the 60th part of a minute, whether of an hour or of a degree. The minutes, being

the first divisions of these units, are called in the old mathematical treatises "primes," and were marked thus ', the seconds (*minutæ secundæ*) thus ". The next sexagesimal division was called thirds. The time divisions are now commonly marked m. and sec.

SECOND ADVENTISTS, or **Adventists**, a religious sect who believe in the speedy second advent of Christ and the end of the world. They owe their origin as a body in the United States to William Miller. (See MILLER, WILLIAM.) Under his preaching and that of some of his followers, the number of adherents rapidly increased. The time at which they at first expected the second appearing of Christ was October, 1842, and subsequently some of them have fixed upon different dates, among others 1843, 1847, 1848, 1857, and 1861. In 1840 Joshua V. Himes, one of their preachers, began the publication in Boston of a semi-monthly journal in advocacy of their views, called the "Signs of the Times and Exposition of Prophecy," and two years later changed it to a weekly, called the "Advent Herald," which had a very large circulation. The number of members continued to increase, notwithstanding the repeated errors into which they fell in regard to the date of the second advent. After the death of Mr. Miller (1849) there was some division in their views, a part holding to some modification of the usual Trinitarian view of the divinity of Christ, and some of them adopting the doctrine of the annihilation of the wicked; while the remainder adhered to the usual views of Trinitarians, except as to the second coming of Christ, which they believe will be speedy and pre-millennial, and that the first resurrection, that of the righteous, will then occur, while the wicked will not be raised till 1,000 years later; that during this thousand years he will reign on the earth, and while his reign will be a period of happiness for the righteous, it will be one of terror and judgment for the wicked. The Adventist churches are entirely independent, and generally receive their members by immersion on a profession of faith.—The "Advent Christian Association" is a body of Adventists who believe in the final destruction of the wicked. At the 16th annual meeting of this body, held at Springfield, Mass., in August, 1875, it was resolved, in order to complete the congregational form of government which has been adopted by the denomination, to convoke at once a general conference. The chief organ of this denomination is the "World's Crisis," edited by John Couch and Miles Grant. The "American Millennial Association," founded in Boston in 1858, is the centre of the "evangelical" Adventists, who do not believe in the final destruction of the wicked. Their principal organ is the "Messiah's Herald," published at Boston. The "Life and Advent Union" is another organization of Adventists believing in the annihilation of the wicked. Its organ is the "Herald of Life," published at Springfield, Mass.—Another branch

of Adventists observe the seventh day as the sabbath, and are called Seventh Day Adventists. They originated as early as 1844. They set no time for the coming of the Lord Jesus Christ, believing that the prophecies which, in the opinion of other Adventists, fix the second advent in or about the year 1844, really brought the world only to the "cleansing of the tabernacle," a period of brief but uncertain duration preceding the coming of Christ. One of the first organizers of this movement, Elder James White, began in 1850 the publication of the first organ of the Seventh Day Adventists, the "Advent Review and Herald of the Sabbath," which in 1855 was removed to Battle Creek, Mich., which place was henceforth the centre of all the denominational interests. The "Seventh Day Adventist Publishing Association" published in 1874, at Battle Creek, four denominational papers in English, one in Danish, and one in Swedish. Another English paper was established in California in 1874. The churches are organized into state conferences, of which in 1875 there were 13. A general conference, consisting of delegates, ministers, and laymen, meets annually. A mission has been established in Switzerland, where 200 believers were reported in 1875. The general conference of 1875 resolved to send missionaries as soon as possible to Great Britain, France, Germany, Holland, Italy, Hungary, Africa, and Australia. Strict temperance views, including the prohibition of the use of tobacco, prevail, and abstinence from pork, tea, and coffee is recommended. According to a report made to the general conference of 1875, the number of ministers was 69, of churches 339, and of members 8,022.

SECRETARY BIRD, a rapacious bird of the genus *serpentarius* (Cuv.) or *gypogeranus* (Ill.). The bill is moderate, broad, elevated at the base, and the culmen much arched to the hooked tip; nostrils with large and oblique lateral opening; wings long, with the third, fourth, and fifth quills nearly equal and longest, armed on the wrist joint with an obtuse spur; tail very long and wedge-shaped, with the two middle feathers prolonged; tarsi much lengthened, slender, covered in front with transverse scales; toes very short, the anterior ones united at base by a membrane, the hind one rather elevated, and all covered above with transverse scales; claws nearly straight and blunt; the lores and space round the eyes naked. The best known species is the *S. reptili-vorus* (Daud.; *gypogeranus serpentarius*, Ill.), about 3 ft. long, inhabiting the sandy plains of S. Africa; the general color is bluish gray, the quills, thighs, crest, and abdomen more or less marked with black; the throat and chest shaded with white, and lower tail coverts reddish; cere and naked parts yellow; it has a long erectile crest on the back of the head, looking when depressed like a pen behind a clerk's ear, whence the common name; it is also called serpent eater from its favorite food,

and messenger from its long steps and rapid gait. These birds are usually seen in pairs, and devour serpents and other reptiles; when attacking a serpent they approach with one

Secretary Bird (*Serpentarius reptilivorus*).

wing extended and acting as a shield to the body, and with the other strike the reptile, wounding it with the wing spur, tossing it into the air, and safely wearying out the most venomous species; they also eat lizards, tortoises, rats, small birds, and large insects. They run and hop very swiftly; they are very voracious, Le Vaillant mentioning that he took from the crop of one 11 good-sized lizards, 3 serpents as long as his arm, 11 small tortoises ("many of which were about 2 in. in diameter"), and a number of insects. They are often introduced, partly domesticated, into poultry yards to rid them of rats, snakes, and other animals which devour young birds or eggs, and they rarely attack the fowls while supplied with reptiles and meat. The nest is made on trees, and is large, built of sticks and lined with wool and feathers; they lay two or three eggs. This bird in its long tarsi resembles the waders, and has been placed among them by Vieillot, and among the *gallinæ* with the bustard by others on account of the wing spurs, terrestrial habits, and some details of internal structure. If a raptorial bird, as Nitzsch maintains, it comes nearer the vulture than the falcon family in the naked cheeks, loose plumage about the head, straightness and bluntness of the claws, and greater webs between the toes. A species is found in the Philippine islands, which is probably distinct from the African bird.

SECRETION. See GLAND.

SECTOR, in geometry, the portion of the area of a circle included between two radii and an arc. The instrument called by this name is used for solving mechanically numerous questions of proportions in geometry and trigonometry. It is called by the French the compass of proportion. It is made of two strips of

ivory, wood, or metal, each of them 6 in. or a foot long, and is hinged in the centre like a carpenter's rule. The pivot represents the centre of the circle, and the lines drawn from it upon the two limbs the radii. Upon these lines are drawn the several scales specially adapted to the sector. Other scales not directly belonging to it may be placed in the blank spaces on the limbs. The scales for the radial lines are selected and arranged according to the particular uses for which the instrument is intended. They commonly consist of a line of chords by which we may protract an angle of any number of degrees, find the degrees corresponding to any arc, &c.; a scale of equal parts, which affords the means when the limbs are opened to the proper extent of finding with a pair of dividers a third proportional to two given lines, or a fourth to three given lines, &c.; also lines of sines, secants, tangents, and polygons. The sector is a convenient instrument in plotting for giving without calculation angles and the lengths of required lines; but all instruments are necessarily imperfect, and since the introduction of logarithmic tables this one is little used.—An instrument called the astronomical or equatorial sector is used for taking the difference of right ascensions and declinations of stars; and the zenith sector is used in trigonometrical surveys to determine the zenith distances of stars whose declinations differ little from the latitude of the observer.

SECULAR GAMES, in Roman history, games celebrated at long and irregular intervals. Under the republic they were known as the Tarentine games from a place in the Campus Martius, called Tarentum, where they were celebrated, and appear to have been instituted about the time of the consul Valerius Publicola. Nothing is known of their origin beyond the fact that they were celebrated in honor of Pluto and Proserpine for the purpose of averting from the state some great calamity. Down to the time of Augustus they were held but three times; they were revived by that emperor in 17 B. C. with considerable pomp, occupying three days and nights, and being accompanied by sacrifices to Jupiter, Juno, and all the superior deities. For this occasion Horace wrote his *Carmen Sæculare*. The secular games were celebrated in the reign of Claudius in A. D. 47, in that of Domitian in 88, and in that of Philip in 248.

SECULARISM. See HOLYOAKE, GEORGE JACOB.

SECUNDUS, Johannes. See JOHANNES SECUNDUS.

SÉDAINE, Michel Jean, a French dramatist, born in Paris, July 4, 1719, died there, May 17, 1797. He was a stone cutter, but became known in 1756 by his comic opera *Le diable à quatre*, for which Philidor composed the music. Among his other pieces, set to music by Grétry and others, was *Richard Cœur de Lion* (1784). His best comedy, *Le philosophe sans le savoir* (1765), was revived in 1875, at the Théâtre Français.

SEDALIA, a town and the county seat of Pettis co., Missouri, on the Missouri Pacific railroad, at the junction of the Lexington branch, and the Missouri, Kansas, and Texas railroad, 189 m. by rail W. of St. Louis, 64 m. W. by N. of Jefferson City, and 94 m. E. S. E. of Kansas City; pop. in 1870, 4,560, of whom 845 were colored; in 1875, about 8,000. It was laid out in 1860, on one of the highest swells of a rolling prairie. The principal street is 120 ft. wide, is finely shaded, and has many handsome buildings. Sedalia is lighted with gas, and is supplied with water by the Holly system. It has a large and rapidly increasing trade. It contains the shops of the two railroad companies, several founderies and machine shops, flouring mills, and manufactories of agricultural implements, carriages, soap, and woollens. There are three hotels, two national banks, good public schools, a public library and reading room, three daily and four weekly newspapers, and 11 churches.

SEDAN (anc. *Sedanum*), a fortified town of France, in the department of Ardennes, on the right bank of the Meuse, 130 m. N. E. of Paris; pop. in 1872, 14,345. It has fine squares and promenades, a Protestant and three Catholic churches, and a château in which Turenne was born. Fine black cloths and cassimeres, linen, hosiery, leather, hardware, and firearms are manufactured. Sedan was formerly the capital of a principality, which in 1591 came into possession of the Turenne family, who in 1642 ceded it to France. It had a celebrated Protestant university, which was suppressed on the revocation of the edict of Nantes in 1685. The chairs commonly known as sedans took their name from this town. The fortress surrendered to the Hessians in 1815, and was occupied by the Prussians till November, 1816. Here the Germans, on Sept. 1, 1870, obtained a victory over the French, which led to the capitulation of the fortress, and the capture of Napoleon III. and his army. (See FRANCE, vol. vii., p. 397.)

SEDGE (A. S. *seeg* or *sæg*, a dagger, formerly applied to sharp-pointed plants in general which grew in marshes), a name for plants of the genus *Carex*, but sometimes applied in a general way to other plants of the *Cyperaceæ*, or sedge family, to which it belongs. There are about 200 species of the genus *Carex* in North America; they are found in great abundance in wet places (though some are met with only in dry localities and on the tops of mountains), where they form a large portion of the vegetation, and are often mistaken for grasses, from which they differ in several important particulars. The sedges are perennial, and, especially those in wet localities, often form dense tufts or tussocks; the culms or stems are triangular and solid; the leaves are grass-like, often rough on the margin and keel, with the sheaths (which in grasses are generally split down on one side) quite closed or entire;

at the upper portion of the stem are leafy or scale-like bracts, in the axils of which are borne the flower spikes, which are also terminal. The stamens and pistils are in separate

A Sedge (*Carex umbellata*), with separate Perigonium and Bract, Pistil, and section of Ovary.

flowers, either on the same spike (androgynous), or on separate spikes on the same plant (monocious), or rarely on distinct plants (dioecious). Both kinds of flowers are subtended by a scale-like bract, and these scales overlap one another equally around the axis to form a more or less cylindrical (sometimes ovoid) spike. The staminate flowers consist of three (rarely two) stamens to each bract; the pistillates have a single ovary and two or three long stigmas; the ovary is enclosed in a bag or sac with a narrow orifice from which the styles are protruded; this bag (*perigynium*) increases with the ripening fruit, and in some species becomes large and bladders; the fruit is a lens-shaped, plano-convex or triangular akene. The carices vary in height from a few inches to 3 ft. and over; in some the stems are weak and thread-like, and in others very wiry and rigid; they flower for the most part early in spring, and perfect their fruit during the summer. It is estimated that there are in all about 1,000 species, which are more abundant in arctic and cold countries, and diminish toward the tropics, where they are found only in the mountainous portions. While the species are numerous, the number of individuals is also very great, and in many places they form a large share of the vegetation; but they are of little direct value to man; their stems and foliage are dry and harsh, and contain very little sugar or starch; their chief office is to furnish mould for the sustenance of other plants. They can hardly be regarded as weeds, though some make their appearance in pastures which are too wet for the growth of nutritious grasses; the large tussocks which the sportsman and botanist

uses as "stepping stones" in crossing swamps are mostly produced by *C. striata*, in some of its several forms.—The sand sedge (*C. arena-ria*), common on the shores of Europe, has a slender but strong running and branching root stock, several feet long, which serves to bind the sands where it grows naturally, and is planted for the same purpose upon the dikes in Holland; the roots of this species have a reputation for diuretic and sudorific properties, and are known in Europe as German sarsaparilla. The Laplanders are said to convert the leaves of *C. sylvatica*, by drying and carding, into a sort of vegetable wool, which they use as a non-conductor of heat, to stuff their winter shoes. In some localities carices form a considerable part of the marsh hay which is cut for use as a mulch, and for bedding animals in the stable; when saturated with urine, it is thrown upon the manure heap and soon converted into a fertilizer. The carices, though regarded by novices in botany as difficult, have been favorite objects of study by some of the most eminent botanists. An important monograph on the American species was published by Schweinitz and Torrey in the "Annals of the New York Lyceum of Natural History" in 1824; later the species of the northern states were elaborated for Gray's "Manual of Botany" by John Carey; numerous papers on the genus by the late Dr. Chester Dewey are to be found running through the "American Journal of Science," in which the number of species is increased to an extent not accepted by other botanists; and Mr. S. T. Olney of Rhode Island has made important contributions to our knowledge of these plants. One of the finest monographs upon any specialty in botany is the "Illustrations of the Genus *Carex*," by Francis Boot (4 vols. fol., London, 1858-'67), with 600 plates.

SEDGWICK, a S. county of Kansas, intersected by the Arkansas river, and drained by the Little Arkansas and other affluents of that stream; area, 1,512 sq. m.; pop. in 1870, 1,095. The southwestern branch of the Atchison, Topeka, and Santa Fé railroad terminates at the county seat. The surface is undulating and the soil fertile. The chief productions in 1870 were 6,652 bushels of wheat, 1,100 of oats, 1,290 of potatoes, and 2,000 lbs. of wool. There were 407 horses, 760 cattle, 307 sheep, and 165 swine. Capital, Wichita.

SEDGWICK, Adam, an English geologist, born at Dent, Yorkshire, about 1785, died in Cambridge, Jan. 27, 1873. He graduated at Trinity college, Cambridge, in 1808, became a fellow of the college, and in 1818 succeeded Hailstone as professor of geology. He was elected a fellow of the royal society in 1819, and from 1829 to 1831 was president of the geological society. In 1827 he made a geological tour of Scotland, and in 1829, in conjunction with Murchison, visited different portions of Germany, Austria, and Switzerland, especially studying the Alps. In 1831 he commenced

a critical survey of the lower palæozoic strata of England and Wales. He first applied the term Cambrian to a series of rocks intermediate between the Silurian of Murchison and the subjacent crystalline schists and granites; and a bitter controversy arose between the two geologists respecting the use of the terms Cambrian and Silurian. (See GEOLOGY, and MURCHISON.) In 1834 Prof. Sedgwick became prebendary of Norwich. Besides numerous contributions to the transactions of societies, he published "Discourse on the Studies of the University of Cambridge" (1850), and "A Synopsis of the Classification of the Palæozoic Rocks" (1855). He was a strenuous opponent of the theory of evolution, and attacked Darwin's "Origin of Species." For detailed accounts of his researches, see "Memoirs of Sir Roderick I. Murchison," by Archibald Geikie (2 vols., London, 1874), and "Chemical and Geological Essays," by T. Sterry Hunt (Boston, 1875).

SEDGWICK, John, an American soldier, born in Cornwall, Conn., Sept. 13, 1813, killed at Spottsylvania Court House, Va., May 9, 1864. He graduated at West Point in 1837, was appointed second lieutenant in the second artillery, served in Florida, in the removal of the Cherokee nation, and on the northern frontier, and became first lieutenant in 1839. In the war with Mexico he was successively brevetted captain and major for gallantry at Contreras and Churubusco and at Chapultepec. In 1855 he was commissioned major in the first cavalry. He was made a brigadier general of volunteers on Aug. 31, 1861, received command of a division of the army of the Potomac in March, 1862, participated in the peninsular campaign, was wounded at Glendale, June 30, and was appointed major general of volunteers July 4. At the battle of Antietam, Sept. 17, he was severely wounded. On Dec. 22 he took command of the 9th army corps, and on Feb. 5, 1863, was transferred to the 6th corps of the army of the Potomac. He was in command at the storming of Marye's heights, near Fredericksburg, and in the final battle near Chancellorsville, May 3, 4; and in the Pennsylvania campaign he made a forced march of 35 m. to Gettysburg, where he commanded the left wing of the army in the battle of July 2, 3, and took part in the pursuit of the enemy to Warrenton. In the Rapidan campaign, September to December, he commanded the right wing, composed of the 5th and 6th corps, and was engaged in the combat of Rappahannock station, Nov. 7, and in the operations at Mine run, Nov. 26 to Dec. 3. In the Richmond campaign in May, 1864, he commanded the 6th corps, which had become known as Sedgwick's corps, and took part in the battle of the Wilderness, May 5, 6. Three days later, while making a personal reconnaissance, and directing the placing of a battery for the battle of Spottsylvania Court House, he was shot by a sharpshooter.

SEDGWICK. I. Theodore, an American statesman, born in Hartford, Conn., in May, 1746, died in Boston, Mass., Jan. 24, 1813. After a partial course at Yale college, he studied law, and in April, 1766, was admitted to the bar, and began practice at Sheffield, Berkshire co., Mass., which he represented several times in the legislature. In 1776 he served as aid to Gen. Thomas in the expedition to Canada. About the close of 1785 he removed to Stockbridge, and in that year and the next was a member of the continental congress. In the winter of 1787 he took a leading part in the suppression of Shays's rebellion. In 1788 he was a member of the Massachusetts convention which ratified the federal constitution, and speaker of the house of representatives of the state. He was a representative in congress from 1789 to 1796, and U. S. senator 1796-'9, and in 1799 again a representative and speaker of the house. In 1802 he was appointed to the bench of the supreme court of Massachusetts, where he remained till his death. Judge Sedgwick was an active member of the old federal party, and was ardently hostile to slavery. Shortly after the adoption of the Massachusetts constitution (1780), Elizabeth Freeman, a negro woman belonging to a Mr. Ashley of Sheffield, having fled in consequence of ill treatment, her master sued to regain his slave. She was defended by Mr. Sedgwick, and by the decision of the court pronounced free. This, it is believed, was the first fruit of the declaration in the Massachusetts bill of rights that "all men are born free and equal," and led to the extinction of slavery in that state.

II. Theodore, an American lawyer, eldest son of the preceding, born in Sheffield, Mass., Dec. 31, 1780, died in Pittsfield, Nov. 7, 1839. He graduated at Yale college in 1798, was admitted to the bar in 1801, and practised at Albany, N. Y., till 1821, when he retired to Stockbridge. He was a member of the state legislature in 1824, 1825, and 1827, and carried through a bill for a railroad across the mountains from Boston to Albany. He advocated free trade, temperance, and anti-slavery, and published "Hints to my Countrymen" (1826), and "Public and Private Economy, illustrated by Observations made in Europe in 1836-'7" (3 vols. 12mo, New York, 1838).—His wife, SUSAN RIDLEY (died 1867), was the author, among other works, of "The Morals of Pleasure" (1829); "The Young Emigrants" and "The Children's Week" (1830); "Allen Prescott" (1835); "Alida" (1844); and "Walter Thornley" (1859). **III. Catharine Maria**, an American authoress, daughter of Judge Theodore Sedgwick, born in Stockbridge, Mass., in 1789, died near Roxbury, July 31, 1867. She published "The New England Tale" anonymously in 1822, and it had an immediate and wide popularity. In 1824 she published "Redwood," which was republished in England, and translated into French, Italian, German, and Swedish. Her subsequent publications in-

clude "Hope Leslie, or Early Times in America" (1827); "Clarence, or a Tale of our own Times" (1830); "Le Bossu," a story for the young (1832); "The Linwoods," a romance of the revolution, and a collection of tales (1835); a series of juveniles, including "The Poor Rich Man and Rich Poor Man," "Live and Let Live," "Means and Ends," "Home," and "Love Token for Children" (1836-'9); the life of Lucretia Maria Davidson, in Sparks's "American Biography" (1837); "Letters from Abroad to Kindred at Home," after a visit to Europe (1841); "Wilton Harvey, and other Tales" (1845); and "Married or Single?" (1857).—See "Life and Letters of Miss Sedgwick," edited by Mary E. Dewey (New York, 1871). **IV. Theodore**, an American lawyer, son of Theodore Sedgwick, 2d, born in Albany, N. Y., Jan. 27, 1811, died in Stockbridge, Mass., Dec. 9, 1859. He graduated at Columbia college, New York, in 1829, and was admitted to the bar in May, 1833. The next 15 months he passed in Europe, chiefly at Paris, where he was attached to the legation of Edward Livingston. On his return home he commenced practice in New York, which he prosecuted with great industry and success till about 1850. He published a memoir of William Livingston (1833); "Treatise on the Measure of Damages, or an Inquiry into the Principles which govern the Amount of Compensation recovered in Suits at Law" (1847; 5th ed., 1869); and a "Treatise on the Rules which govern the Interpretation and Application of Statutory and Constitutional Law" (1857). In January, 1858, he was appointed United States attorney for the southern district of New York. He edited the political writings of William Leggett (2 vols. 8vo, New York, 1840).

SEDELEY, Sir Charles, an English poet, born at Aylesford, Kent, in 1639, died Aug. 20, 1701. He was the son of Sir John Sedley, and after the restoration went to London, where according to Wood he set up for a satirical wit. He soon obtained great favor with Charles II., and his private fortune was wasted in debauchery. He was once engaged in a riot at a public house, where he made a speech to the mob, naked, from the balcony, and was fined £500. He now applied himself to serious business, and distinguished himself in parliament by his opposition to James II. His activity in bringing about the revolution is attributed to the king's intrigue with his daughter, who became his mistress and was created countess of Dorchester. His collected works, consisting of short amatory poems, parliamentary speeches, plays, and some translations from the classics, were published with a memoir in 1722.

SEDUCTION, the persuading a woman to surrender her chastity. It has been often made a reproach to the common law that it does not regard the seducer as a criminal, or at least hold him to a direct responsibility. The French and Prussian codes also, composed as they have

been by the deliberate act of the lawgivers, though, like the Roman laws, they throw the strongest defences against violence around the chastity of women, yet denounce no penalties against the mere seducer. But though the common law does not hold the seducer to any direct responsibility, yet indirectly it does reach him. The seducer who renders a female servant incapable of her usual labor and service is bound to make indemnity. This is the principle and basis of almost all suits for seduction; they are actions on the case, and rest immediately on the loss of service consequent upon the seduction. By a fiction of the law the relation of master and servant is conceived to exist between parent and child, and thus a father may have an action for the seduction of his daughter. The father may also found his suit on the seducer's illegal entry upon his premises, and may then state the seduction and loss of service in aggravation. But it is essential to this mode of proceeding that the daughter lived with the father at the time of the seduction, or, if away, was subject to recall at his will; and it is therefore inapplicable to very many cases. In the more usual form to which we have referred, namely, of case, the consequential injury being the ground of action, it is unimportant whether the seduced lived with the father at the time of the seduction or not.—It is now the general rule that exemplary or punitive damages are properly given in such a case, and the amount of them is very much in the discretion of the jury. One of the earliest cases in which such damages are recommended by the court is a case of the year 1800, in which Lord Eldon, at that time chief justice of the common pleas, told the jury they were to regard not merely the loss of service but the wounded feelings of the parent. In 1805 Lord Ellenborough said that redress was to be given to the father not only for his loss of the society and comfort of his child, but also for the dishonor which he received; and in 1811 that, though it was difficult to conceive on what legal principle the damages could be extended beyond the injury resulting from loss of services, yet the practice was now inveterate and could not be shaken, and that the feelings of parents and of those who stood *in loco parentis* were always to be taken into consideration. In all cases then, if the suit is at the common law, however the damages may be increased by other considerations, some loss of service must always be alleged in the declaration, and proved. The English law requires that the actual relation of master and servant shall have existed between the plaintiff and the person seduced at the time of the seduction; so that where a daughter under age was seduced by her master, while living in service away from her father's house with his consent, and with no intention of returning to it, the father was held to have no ground of action. The rule is not so strict in the United States; and in a leading case in New York, where a daughter

under age, with the consent of her father, lived with her uncle, who agreed to pay her for such work as she chose to do, but made no agreement with her for any fixed time of service, and while in her uncle's house she was seduced and returned to the house of her father, who paid the expense attending her confinement, it was held that, as the father had made no contract binding out his daughter, he could still control her services; the fact that the daughter had no intention of returning could not affect the father's right; she was his servant *de jure*; and as the defendant had done an act which deprived the father of services that he had the right to exact, he must respond in damages.—The father's legal right to the services of his daughter extends to her majority, which at the common law is the age of 21 years. If she is living with her father during her minority, proof of this fact alone suffices to maintain the issue in respect to the fact of service; service is presumed. If the daughter is already of full age, there must be proof of service in fact rendered to the father. Proof of very slight service suffices, if she is still living with him; but if she is absent from home under a contract made by herself since attaining her majority, the father has no right of suit. His action, however, will not be defeated if the defendant hired the daughter for the purpose of getting her into his possession and out of the father's control, even though she were of full age at the time of the hiring, provided she were then living in her father's family. The hiring being fraudulent and therefore null, the relation of master and servant was never contracted between the daughter and her seducer, and so was never interrupted as between her and her father.—The action may be maintained by any one who stands *in loco parentis*, by a guardian, for example, or by a relative who has adopted the female as his own child, in the same cases and under the same conditions that give a cause of action to the natural parent. A mother cannot maintain an action for the seduction of her daughter during the father's life, though the child be not born until after the father's death. There must be an actual or constructive right to the daughter's service at the time the injury is committed, that is to say, at the time of the seduction. If the relation of master and servant first arises after the injury has been done, there is no ground to claim indemnity for the resulting loss of service.—Upon the trial of the cause, the fact of the seduction may be proved by the woman herself. Her general character for chastity is considered to be in issue, and may be impeached by general evidence on the part of the defendant, and be supported by the plaintiff in like manner. But though the evidence discloses the woman's previous criminality with others, it will avail nothing if the jury are satisfied that the defendant is the father of her child, and so the cause of the plaintiff's loss of service. It has been held that if an attempt

be made by the defendant to destroy on trial the good character of the seduced woman, and this attempt be defeated, the making the attempt may be regarded by the jury in estimating damages; and so indeed may all circumstances which aggravate the seduction, and increase the harm caused by it.—Recent statutes have made great inroads on the common law of seduction in several of the states. The action is allowed to be brought by the father or other near relative, irrespective of any question of the right to service, and in some states even by the woman herself. It is also in some of the states made a felony. The terms in which the offence is described differ in different statutes, some providing for the punishment of any man who shall "seduce and debauch any unmarried woman," while others make a promise of marriage an essential element of the seduction. In respect to the promise of marriage, it has been held not necessary to aver a mutual or valid promise. It is therefore immaterial that the seducer is a married man, provided the woman was ignorant of it.

SEDUM (Lat. *sedere*, to sit, in allusion to the manner in which some of the plants are attached to rocks), the name of a genus of plants some of which are known as orpine, stonecrop, and live-for-ever, while the botanical name is in common use for the ornamental species. It belongs to the family *crassulaceæ* with several other genera of mostly succulent plants, one of which, *sempervivum*, is described under HOUSELEEK. The sedums include annual and perennial plants of very variable habit; some are low and creep along the ground, forming moss-like tufts, while others are erect, and a few are somewhat woody; the leaves are fleshy, and variable in shape, being cylindrical and linear, or flat and broad, and both opposite and alternate; the flowers, mostly in cymes, are white, yellow, and rose-colored; the petals, sepals, and pistils are four or five, and the stamens twice that number, the mostly distinct ovaries ripening into many-seeded pods. About six species are indigenous to the Atlantic states, and two have been introduced

Live-for-ever (*Sedum telephium*).

from Europe, one of which, *S. telephium*, the live-for-ever, has long been a garden plant, and has become naturalized as a troublesome weed in various parts of the country. Its strong

stems form a dense clump 2 ft. high; the large oval leaves are toothed on the margins; the flowers are pale purple in a dense terminal cluster, and appear in July. This, like many others of the species, is very tenacious of life; a stem cut and pinned up against the wall will continue to grow, and even flower, at the expense of the nutriment contained in the lower leaves and the base of the stem; it is often called Aaron's rod, and in England it is known as midsummer-men; the country girls on midsummer's eve set up two stems of it, one for themselves and the other for their lover; the fidelity of the lover is estimated by his plant turning to theirs. In Europe it has a reputation as a remedy for diarrhœa, being mucilaginous and slightly astringent.—Stonecrop

Stonecrop (*Sedum acre*).

(*S. acre*) naturally grows upon rocks and walls; it is a low moss-like species, forming a dense mat of light green, and producing numerous yellow flowers in July. It has long been cultivated, and is sometimes used for edgings, and often to cover the earth in flower vases, hanging baskets, and the like; it has also become naturalized. It is exceedingly acrid to the taste, and one of its common names in England is wall pepper; it is emetic and cathartic in large doses, and if the bruised leaves be kept long in contact with the skin a blister will be produced.—Among the native species is *S. ternatum*, with low spreading stems, flat wedge-shaped leaves, and ternate or three-spiked cymes of white flowers, is found from Pennsylvania south and westward, and is often cultivated. The showiest native species, properly named *S. pulchellum*, as it is one of the handsomest of the genus, is a more southern plant; its stems, often a foot high, are crowded with linear cylindrical leaves, and at the top bear a broad cyme, the spikes of which are arranged in a very regular manner, and bear a profusion of rose-purple flowers; it is now and then cultivated, and in some localities is known as the widow's cross. Rose-root (*S. rhodiola*) is a dioecious species with greenish yellow and purplish flowers, and a rose-scented root; it grows sparingly in Pennsylvania, but is plenty on the extreme

eastern coast. Several sedums are peculiar to the far west and the Pacific coast. About 125 species in all are enumerated, some being only of botanical interest, while several are prized in cultivation. One, under the name of *S. carneum variegatum*, is a popular garden

Sedum Sieboldii.

plant; it is of low growth and has its small leaves edged with white; nothing is known of its origin, and it has not produced flowers.—The Japan sedum, *S. spectabile* (called in the catalogues *S. Fabaria*) is a fine species, 12 to 18 in. high, with rose-purple flowers in dense cymes, which are 6 in. across; it is especially valuable on account of blooming in September, when flowers of delicate tints are scarce. Another Japanese species is Siebold's sedum (*S. Sieboldii*), with slender stems, which soon become prostrate, and nearly round leaves in whorls of three,

of a fine glaucous green; the terminal cymes of pink or purplish flowers open in October; there is a variegated form in which the leaves are distinctly marked with yellowish white; though perfectly hardy, both the plain and the variegated forms are seen to much better advantage if grown as house plants, in a hanging pot or a vase. The sedums are easily multiplied by dividing the clump or making cuttings of the stems.

SEEBACH, Marie, a German actress, born in Riga, Feb. 24, 1835. She is the daughter of an actor, and was educated at Cologne for the opera. After appearing in minor parts in Nuremberg and Cassel, chiefly in vaudevilles, she became celebrated by her personation of Margaret in Goethe's *Faust* and of Clärchen in *Egmont* in Hamburg, Munich, Vienna, and Hanover. She performed chiefly at Hanover from 1856 to 1865, when she and her husband, the tenor singer Albert Niemann, removed to Berlin. She was afterward divorced, and in 1870-'71 made a tour of the United States.

SEELAND (Dan. *Spølland*), an island of Denmark, bounded N. by the Cattegat, separated E. by the Sound from Sweden, S. by the Baltic from the islands of Möen, Falster, and Laaland, and W. by the Great Belt and its continuations from Langeland, Fünen, and Samsø; length 81 m., greatest breadth 66 m.; area, 2,721 sq. m.; pop. in 1870, 560,510. It is irregular in shape and much indented by arms of the Baltic, and in the north an arm of the Cattegat extends far into the interior. The surface is generally flat. The soil is an extremely fertile alluvium resting on beds of

mussel shells and corallines. The chief product is grain. Extensive forests once covered the island, but timber is now scarce. The climate is humid and milder than in other places in the same latitude. Frederiksborg, the new part of the city of Copenhagen, stands on this island, which together with Möen and Samsø forms one of the main divisions of Denmark.

SEELEY, John Robert, an English author, born in London about 1834. He is the son of a London publisher. He graduated at Christ Church, Cambridge, of which he became a fellow in 1858, was for several years principal classical assistant at the city of London school, was appointed in 1863 professor of Latin in University college, London, and in 1869 was made professor of modern history at Cambridge. In 1865 he published anonymously "Ecce Homo: The Life and Work of Jesus Christ." He has also published "Classical Studies, as an Introduction to the Moral Sciences" (1864); "An English Primer, or Course of English Instruction for Schools," with E. A. Abbott (1869; Boston ed., "English Lessons for English People"); "Roman Imperialism" (Boston, 1869); "Lectures and Essays" (1870); and an edition of Livy.

SEELYE, Julius Hawtrey. See supplement.

SEEMANN, Berthold, a German naturalist, born in Hanover, Feb. 28, 1825, died in Nicaragua, Oct. 10, 1871. In 1846 he was appointed naturalist to an English expedition around the world, which returned to London in 1851. He explored the Feejee islands in 1860, and purchased a gold and silver mine in Nicaragua. His principal works are: "Narrative of the Voyage of H. M. S. Herald, and three Cruises to the Arctic Regions in search of Sir John Franklin" (London, 1852; German, 2 vols., Hanover, 1853); "Botanical Researches" (London, 1852-'7); "Popular History of the Palms" (1856); "Viti, an Account of a Government Mission to the Vitian or Fijian Islands" (1862); and "Dottings of the Roadside" (1868).

SEGNERI, Paolo, an Italian orator, born at Nettuno in the Roman Campagna, March 21, 1624, died in Rome, Dec. 9, 1694. He early joined the order of Jesus, and labored as a missionary in Italy from 1665 to 1692, when he was appointed by Innocent XII. preacher to the papal court. His principal works are: a course of Lenten sermons entitled *Il Quarosimale* (fol., Florence, 1679; 4to, Rome, 1752; 3 vols. 8vo, Padua, 1826); *Il Cristiano istruito* (3 vols. 4to, Florence, 1686; French translation, 5 vols., Avignon, 1836); *Il incredulo senza scusa* (Florence, 1690); *Panegirici sagri* (Venice, 1692); and *Prediche dette nel palazzo apostolico* (4to, Rome, 1694). Complete editions were published at Venice (4 vols. 4to, 1712, 1758), Parma (3 vols. fol., 1714, with a life by Maffei), and Milan (3 vols. 8vo, 1837-'8).

SEGOVIA. I. A central province of Spain, in Old Castile, bordering on Valladolid, Burgos, Soria, Guadalajara, Madrid, and Ávila; area, 2,714 sq. m.; pop. in 1870, 150,812.

The S. E. portion is mountainous, being bordered by the Guadarrama chain, and the remainder in general level. It is watered by the Eresma and several other tributaries of the Douro. Some fine marbles are quarried, besides large quantities of limestone, chalk, and granite. The climate is generally cold, and the soil is very fertile. The vine and other fruits are extensively cultivated. The mountainous region contains important pine forests and rich pastures. The manufactures, once flourishing, are now limited to cloth, glass, paper, and wines and brandies, on a small scale. **II.** A fortified city, capital of the province, on the Eresma, 43 m. N. W. of Madrid; pop. about 12,000. It stands on a rocky ridge, occupies two hills and a valley, and is surrounded by dilapidated walls with round towers and seven gates. The streets are tortuous and narrow, lined with lofty and generally antique houses. There are a Gothic cathedral, a handsome mint erected in the 15th century, and five old bridges; but Segovia is chiefly famous for its ancient *alcázar* or Moorish castle, used as the treasury building down to 1730, and since as a school of artillery;

The Alcázar of Segovia.

and for its magnificent aqueduct, attributed to Trajan, with 160 arches in double tiers, three of which are 100 ft. high. The woollen manufactures, once employing 30,000 hands, are now comparatively insignificant. Wool is the staple article of export.—Segovia was found-

ed before the invasion of the Romans, by whom, as well as by the Goths and Arabs, it was embellished. It was occupied by the French from 1808 to 1814.

SEGUIN, Édouard, a French physician, born at Clamecy, department of Nièvre, Jan. 20, 1812. He was educated at the colleges of Auxerre and St. Louis in Paris, studied medicine and surgery, and devoted himself to the treatment of idiots. After the revolution of 1848 he settled in Ohio. In 1860 he revisited his native country, and has since lived in New York. Since 1866 he has done much for the study of animal heat by his publications, new instruments, and methods of thermography. He represented the United States as commissioner on education at the Vienna exhibition in 1873. His works are: *Résumé de ce que nous avons fait pendant quatorze mois*, with Esquirol (Paris, 1839); *Conseils à M. O. sur l'éducation de son enfant idiot* (1839); *Théorie et pratique de l'éducation des idiots* (two parts, 1841-'2); *Hygiène et éducation* (1843); *Images graduées à l'usage des enfants arriérés et idiots* (1846); *Traitement moral, hygiène et éducation des idiots, et des autres enfants arriérés* (1846), the standard authority on the subject; *J. R. Péreire, analyse raisonnée de sa méthode* (1847); *Jacob Rodrigue Péreire, notice sur sa vie et ses travaux* (1847); "Origin of the Treatment and Training of Idiots" (Hartford, 1856); "Idiocy, its Diagnosis and Treatment by the Physiological Method" (Albany, 1864); "Idiocy and its Treatment by the Physiological Method" (New York, 1866); "New Facts and Remarks concerning Idiocy" (1870); "Prescription and Clinic Record" (1870); "Medical Thermometry," with C. A. Wunderlich (1871); "Clinical Charts" (1872); "Thermometry in the Family" (1872); "Manual of Thermometry for Mothers" (1873); *Thermomètres physiologiques, &c.* (Paris, 1873); *Tableaux de thermométrie mathématiques* (1873); and part of his report on education at Vienna (1875). (See IDIOCY.)

SÉGUR. I. Philippe Henri, marquis de, a French soldier, born Jan. 20, 1724, died in Paris, Oct. 8, 1801. He distinguished himself in various battles in 1746-'7, was wounded, and lost an arm; took an active part in the seven years' war, and was finally made prisoner at Closter-camp. In 1763 he was appointed inspector general of infantry, in 1780 minister of war, and in 1783 a marshal. He resigned his office in 1787. During the reign of terror he was imprisoned and lost all his property. Napoleon gave him in 1800 a pension of 4,000 francs. **II. Louis Philippe**, count, a French historian, son of the preceding, born in Paris, Dec. 10, 1753, died there, Aug. 27, 1830. He served under Rochambeau in America in 1782, was appointed ambassador to St. Petersburg in 1784, and was a favorite of Catharine II. He afterward became a brigadier general and ambassador to Berlin, and in 1812 a member of the senate. Under the first restoration he was

a peer, but he rejoined the emperor during the hundred days, and in vain sought to share his exile. His complete works (33 vols., 1824-'30) are chiefly historical, but include plays which he wrote for the Russian empress, under the title *Théâtre de l'Hermitage* (2 vols., 1798), and his *Mémoires, ou souvenirs et anecdotes* (3 vols., 1824; English translation, Boston, 1825). **III. Philippe Paul de**, count, a French historian, son of the preceding, born in Paris, Nov. 4, 1780, died there, Feb. 25, 1873. He entered the army in 1800, became a favorite of Napoleon, who employed him on confidential missions, and for some time was a prisoner of war in Russia. In 1812 he accompanied the emperor in the Russian campaign as his aide-de-camp; and in 1813 he was instrumental in saving the French army at Hanau. Under the first restoration he accepted a commission from Louis XVIII., but joined Napoleon during the hundred days, and was only nominally restored to his rank in 1818. In 1831 Louis Philippe appointed him lieutenant general and peer. His works include *Histoire de Napoléon et de la grande armée pendant l'année 1812* (2 vols., 1824), which involved him in many controversies and in a duel with Gen. Gourgaud; *Histoire de Russie et de Pierre le Grand* (1829); and *Histoire de Charles VIII.* (2 vols., 1834; 2d ed., 1842; English translation, 2 vols., Philadelphia, 1842), a continuation of his father's *Histoire de France*.

SEIDLITZ POWDERS. See ROCHELLE SALT.

SEIDLITZ WATER, the product of certain saline springs in Seidlitz or Sedlitz, a village of Bohemia near Bilin, used as an agreeable and effective aperient. The solid contents in a wine pint, according to Bergman, are 192.8 grains, consisting of sulphate of magnesia, 180 grains; sulphate of lime, 5; chloride of magnesium, 4.5; carbonate of magnesia, 2.5; carbonate of lime, 0.8. To prepare an artificial Seidlitz water, dissolve from $\frac{3}{4}$ to $1\frac{1}{2}$ oz. of sulphate of magnesia in three times its weight of water, and, after filtering, introduce it into a bottle, to be filled with water charged with carbonic acid gas.

SEINE (anc. *Sequana*), a river of France, rising in the department of Côte-d'Or, on the slope of Mt. Tasselot, flowing first N. W., then W. S. W., and again N. W., through the departments of Aube, Seine-et-Marne, Seine-et-Oise, Seine, Eure, and Seine-Inférieure, and falling into the English channel between Havre and Honfleur. The direct distance from its source to its mouth is 250 m., but its windings make it nearly 500 m. long. It is navigable for large vessels to Rouen, and for small vessels 250 m. to Méry-sur-Seine. It is connected by canals with the Loire, the Saône and Rhône, the Somme and Scheldt, and the Ourcq. Its elevation at its source is about 1,500 ft. above the sea. At Paris its width is from 300 to 500 ft., and at its embouchure about 7 m. Its chief tributaries on the right are the Aube, Marne, and Oise, and on the left the Yonne,

Loing, Essonne, Eure, and Rille. The principal towns on its banks are Châtillon, Bar-sur-Seine, Troyes, Nogent, Melun, Paris, Poissy, Mantes, Rouen, and Havre.

SEINE, the metropolitan department of France, in the old province of Île-de-France, entirely enclosed by the department of Seine-et-Oise; area, 183 sq. m.; pop. in 1872, 2,220,060. It is divided into the arrondissements of Paris, St. Denis, and Sceaux, the first of which is coterminous with the city of Paris. The surface is generally level. The Seine flows through the department very circuitously from S. E. to N. W., and the Marne joins it from the eastward. The most valuable mineral productions are excellent building stone and gypsum, producing plaster of Paris. The soil is fertile, and cultivated with great care. Capital, Paris.

SEINE-ET-MARNE, a N. department of France, in the old province of Île-de-France, bordering on the departments of Oise, Aisne, Marne, Aube, Yonne, Loiret, and Seine-et-Oise; area, 2,215 sq. m.; pop. in 1872, 341,490. The surface is undulating, and has many extensive plains. The Seine and the Marne flow through it. It contains sandstone, fine millstones, and potter's clay. The soil is rich and well cultivated. It is divided into the arrondissements of Melun, Meaux, Fontainebleau, Coulommiers, and Provins. Capital, Melun.

SEINE-ET-OISE, a N. department of France, in the old province of Île-de-France, bordering on the departments of Oise, Seine-et-Marne, Loiret, Eure-et-Loir, and Eure, and enclosing the department of Seine; area, 2,164 sq. m.; pop. in 1872, 580,180. The surface is diversified, but there are no high hills. The Seine flows through it, and is here joined by the Oise from the northeast. Millstones, sandstone, paving stone, gypsum, chalk, and potters' clay are found; and there are sulphur springs. The soil is not naturally very fertile, but it is carefully cultivated. The manufactures include cloth, hosiery, paper, firearms, and Sèvres porcelain, the last, which is conducted by the government, being the most important. It is divided into the arrondissements of Versailles, Rambouillet, Corbeil, Mantes, Étampes, and Pontoise. Capital, Versailles.

SEINE-INFÉRIEURE, a N. W. department of France, in Normandy, bounded N. W. by the English channel, E. by the departments of Somme and Oise, and S. by Eure and the embouchure of the Seine; area, 2,330 sq. m.; pop. in 1872, 790,022. It has a generally low surface, the coast being skirted by chalk cliffs of no considerable elevation except near Fécamp, where they are about 700 ft. high, and it is traversed from E. to W. by a low offshoot of the Ardennes. It is watered by the Seine in the southern districts, and by the Bresle, Yères, and Arques in the northeastern. Cotton, linen, cloth, lace, silks, and watch and clock movements are manufactured, and there

are machine works and ship yards. It has important fisheries. It is divided into the arrondissements of Rouen, Havre, Dieppe, Yvetot, and Neufchâtel. Capital, Rouen.

SEISIN. See LIVERY OF SEISIN.

SEISTAN (anc. *Sacastane*, the country of the *Sacæ*), a province in the S. W. part of Afghanistan, with an adjoining part included in Persia. It is between lat. 30° and 32° N., and lon. 61° and 63° E., in the lower basin of the river Helmund. The lake of Seistan, or Hamoon (in its S. W. part known as Lake Zurrah or Zirreh), into which flow the Helmund from the south, the Khash-rud from the east, and the Furrah-rud and the Harut from the north, is a low and swampy expanse from 15 to 30 m. wide, and nearly 200 m. long from N. to S., mainly between the 61st and 62d meridians. A great part of this depressed area, partly included in Persia and Beloochistan, is now dry, though subject to inundation. In the north, near lat. $31^{\circ} 30'$, it is occupied by two shallow and reedy lakes, about 15 m. apart, each of which is also called Hamoon. Seistan proper is a well watered and fertile alluvial plain of sand and clay W. of the Helmund in the lower part of its northward course, bounded S. by the main irrigation canal, and N. and W. by the Hamoon; estimated area, 947 sq. m.; pop. about 45,000, of whom 20,000 are Seistanis, the purest type of Aryan Persians, and 10,000 nomadic Beloochees. The Afghans are few, but politically powerful. Wheat, barley, and melons are produced abundantly, with some cotton, peas, beans, and oil-seeds. Snow rarely falls, but the winters are windy and the mercury sinks to 5° F., rising above 90° in spring and summer. Traces of an elaborate civilization abound, and among the numerous ruins those of Zaranj, the ancient capital as the Arab writers call it, are the most celebrated. The principal existing towns are in the district watered by the main canal; among them is Sekuha, the modern capital. Outer Seistan is 30 m. wide, and extends from the mouth of the Helmund about 120 m. S. along the right or E. bank. It also includes a plain about 80 m. long and 40 m. broad, stretching southward from Seistan proper. The only important town is Charkansur, S. of the Khash-rud, containing a fort and 150 houses.—Seistan was in antiquity a part of Drangiana or Zarangia. It is believed that the Aria Palus of Ptolemy was the lake of Seistan. Some time before the Christian era it was overrun by Scythian hordes, of which the paramount tribe were the *Sacæ*, who gave their name to the country. The Scythians were overcome at the time of the Arab invasion, and Seistan afterward became a province of Persia. It now belongs mainly to Afghanistan. In 1871 an arbitration commission under Sir F. J. Goldsmid fixed the boundary so as to give Persia nearly all of Seistan proper.

SEJANUS, *Lucius Ælius*, a Roman conspirator, born at Volsinii in Etruria, put to death A. D.

31. He was first attached to the interests of the infant Caius Cæsar (Caligula), the son of Germanicus, but shortly after the accession of Tiberius was appointed to the command of the prætorian guard in conjunction with his father, Seius Strabo, who had held the post under Augustus; and when his father became governor of Egypt, the sole command of the prætorian cohort devolved upon Sejanus. As his popularity with the guard increased he aspired to the imperial power. To remove Drusus, the heir of Tiberius, he caused his wife Livia or Livilla to poison him, promising to marry her afterward. He procured the banishment of Nero and Drusus, the sons of Germanicus, and of their mother Agrippina. His wife Apicata had been divorced soon after the death of Drusus, but Tiberius refused to consent to his marriage with Livia. In 26 he induced Tiberius to reside permanently in the island of Capræa, and give himself up to a life of sensual pleasure, and for nearly five years Sejanus acted and was recognized as the representative of the emperor. He was about to hasten the development of his plan when Tiberius, being informed of it, gave the command of the prætorian guard to Nervius Sertorius Macro, and had the death of Sejanus decreed by the senate. He was strangled, and his body was torn to pieces by the populace.

SEJOUR, *Victor*, a French dramatist, born in Paris in 1816, died there, Sept. 20, 1874. His first drama, *Diégarais*, was performed at the Théâtre Français in 1844, and he wrote plays for the Porte Saint-Martin, Odéon, Ambigu, and Gaité theatres, including *Richard III.* (1852), *Les noces vénitienues* (1855), *André Gérard* (for Lemaître's farewell performances, 1857), and *Les fils de Charles Quint* (1864).

SELACHIANS (Gr. *σέλαχος*, a cartilaginous fish), a name applied from Aristotle to the present day to the families of cartilaginous fishes with fixed branchiæ, comprising the rays and sharks, also called plagiostomes. (See **PLAGIOSTOMES**.)

SELBORNE, *Lord*. See **PALMER**, **ROUNDELL**.

SELDEN, *John*, an English author, born at Salvington, Sussex, Dec. 16, 1584, died in London, Nov. 30, 1654. He was educated at Oxford, was called to the bar, and became known as "the great dictator of learning of the English nation." He was a member of Ben Jonson's Literary club. His earliest work, the *Analecton Anglo-Britannicon* (1615), was written in 1606. He also published "England's Epinomis," *Jani Anglorum Facies Altera*, and "The Duel or Single Combat" (1610), law treatises; "Titles of Honor" (1614); *De Diis Syris* (1617); and "History of Tithes" (1618). In the last named work he denied the divine right of the clergy to receive tithes, and was obliged to make a public acknowledgment of his regret at having promulgated his opinions, which however he was careful not to retract. In 1621 he underwent a brief imprisonment for advising the commons to insist upon certain privileges in dispute between themselves and

the crown; and in 1625, being then a member of parliament, he took part against the royal favorite, the duke of Buckingham, whom in the succeeding parliament he aided in impeaching. From 1629 to 1634 he was imprisoned in the tower on a charge of sedition. He had meanwhile produced a variety of works, including his *Marmora Arundeliana* (1628). In 1635 appeared his *Mare Clausum*, in answer to the *Mare Liberum* of Grotius. In the long parliament, to which he was elected in 1640 for the university of Oxford, he frequently sided with the king. He opposed the exclusion of the bishops from the house of peers, and also the condemnation of Strafford, although he was one of the members named to prepare the articles against him. Subsequently he was keeper of the records in the tower, and having subscribed the "Solemn League and Covenant," he was appointed in 1644 one of the 12 commissioners chosen commissioners to the admiralty. When it became apparent that the struggle between the crown and the commons could have no peaceful issue, he gradually withdrew from political life. He died at the house of the countess of Kent, to whom he is said to have been married. He is now best known by his "Table Talk," published in 1689 by Richard Milward, his amanuensis. A complete edition of his works, with a memoir by David Wilkins, appeared in 1726 (6 vols. fol.).

SELENE. See LUNA.

SELENITE. See GYPSUM.

SELENIUM, an elementary substance discovered by Berzelius in 1817 in the refuse of a sulphuric acid manufactory near Fahlun. It resembles sulphur in many of its physical, and tellurium in many of its chemical characteristics. It is always found in combination, its compounds with the metals being called selenides, and they are very rare, the least rare being the selenides of iron, copper, and silver. The symbol of selenium is Se; its atomic weight, 79.5; its specific gravity when crystallized, 4.788; its observed vapor specific gravity at 2,588° F., 5.68. When heated as an amorphous powder to 212° it softens, and when raised a few degrees higher it melts, and on cooling forms a dark brown vitreous solid with a metallic lustre and a specific gravity varying from 4.3 to 4.8. Selenium has neither taste nor smell, and is a bad conductor of electricity. It combines with hydrogen to form seleniuretted hydrogen, which has an offensive odor. The gas is obtained by the action of sulphuric acid on selenide of potassium or iron. Selenium forms with oxygen and water selenious acid, H_2SeO_3 , and selenic acid, H_2SeO_4 , which correspond in composition to sulphurous and sulphuric acids (see SULPHUR), and form salts called respectively selenites and seleniates.

SELEUCIA, the name of numerous ancient cities of Asia, situated in Assyria, Margiana, Syria, Mesopotamia, Cilicia, Pamphylia, Pisidia, Caria, and other countries. **I. Seleucia on the Tigris** was founded by Seleucus I. of Syria,

on the right bank of that river, near its junction with the royal canal of Babylonia, and opposite the mouth of the Delas (now Diala) river, a little S. of the modern city of Bagdad. Commanding the plains of the Tigris and Euphrates, and the principal caravan roads of Assyria and Babylonia, and peopled by settlers from various countries of western Asia, it rapidly rose in wealth and splendor, eclipsing Babylon, until it was in its turn eclipsed by Ctesiphon, built by the Parthians on the opposite bank. The later wars of the Romans against that people proved destructive to Seleucia. It had more than half a million inhabitants in the 1st century, in the 2d was burned by Trajan and Lucius Aurelius Verus, and captured by Septimius Severus, and in the expedition of Julian against the Persians in the 4th century was found deserted. **II. Seleucia Pieria**, a strong fortress of northern Syria, also founded by Seleucus I., was built at the foot of Mt. Pieria, on a rock overhanging the Mediterranean, a few miles N. of the mouth of the Orontes, and W. of Antioch, with which it was simultaneously founded, and of which it formed the seaport. It surrendered to Ptolemy III. of Egypt, was recovered by Antiochus the Great, and in the later period of the Syrian kingdom became independent. Under the Romans it rapidly decayed. Considerable ruins of its harbor, fortifications, and necropolis are still to be seen.

SELEUCUS I., Nicator, the founder of the Syrian monarchy, and of the dynasty of the Selencidæ, born about 358 B. C., assassinated at Lysimachia in 280. He was the son of Antiochus, one of the generals of Philip of Macedon, and accompanied Alexander in his Asiatic expedition. After the death of that monarch he adhered to the fortunes of Perdiccas, but soon after headed his assassins at Pelusium (321). On the second division of the empire he received the satrapy of Babylonia, joined Antigonus against Eumenes, and received from the former the government of Susiana. Antigonus very soon became jealous of his power, and planned his destruction. Seleucus escaped with about 50 horsemen, fled to Egypt, and formed a league with Ptolemy, Lysimachus, and Cassander against the common enemy. Seleucus regained possession of the government of Babylonia in 312, and from this year the Syrian monarchy is reckoned to commence. In 306 he assumed the title of king, and in 302 joined the new league formed by Ptolemy, Cassander, and Lysimachus against Antigonus. The war was ended by the victory of the allies at Ipsus in 301, when Antigonus was killed, and Seleucus obtained all the Asiatic territory conquered by the Greeks, with the exception of lower Syria and western Asia Minor. His empire, extending over about 1,000,000 sq. m., included parts of Cappadocia and Phrygia, Armenia, upper Syria, Mesopotamia, Media, Assyria, Babylonia, Susiana, Persia, Parthia, Bactria, and the territory east-

ward, probably including some parts of India. He founded the city of Seleucia on the Tigris, and removed the seat of government thither; but soon after the battle of Ipsus he made Antioch his capital. The change offended most of his Asiatic peoples, and served to hasten the disintegration of his dominions. The dissatisfaction increased when he divided the empire into 72 satrapies, setting over each a Macedonian or Greek. He afterward allied himself with Demetrius Poliorcetes, the son of Antigonus, whose daughter Stratonice he married; but Demetrius having made himself king of Macedonia, Seleucus joined the alliance against him in 288, and took possession of the greater part of his Asiatic dominions. Demetrius surrendered to him in 286, and remained at Apamea in Syria till his death. At the instigation of the widow of Agathocles, put to death by his father Lysimachus, Seleucus invaded the dominions of his rival with a large army. Lysimachus met him in a decisive battle on the plain of Corus in Phrygia in 281, and was routed and slain. Seleucus now determined to add Macedonia to his dominions, and crossed the Hellespont with a large army, but was assassinated by Ptolemy Ceraunus. He was succeeded by his son Antiochus. He founded Greek colonies in almost every province of his empire.—The dynasty of the Seleucidæ lasted 247 years, from 312 to 65 B. C. The most important successors of Seleucus were his son Antiochus I., 280–261; Antiochus II., 261–246; Antiochus III., the Great, 223–187; and Antiochus IV., Epiphanes, 175–164. The vast empire of Seleucus I. constantly diminished in power and extent, until it was finally absorbed by the Roman empire.—The era of the Seleucidæ, in chronology, is considered as beginning Oct. 1, 312 B. C. It was used in Syria, and by Jewish and Arab historians, until the 15th century.

SELF-DEFENCE. The law requires no man to submit passively to the infliction of violence upon his person. He may always defend himself. If he is assaulted with blows, he may return blows; and if need be he may kill an assailant who attempts, or, rationally considered, seems to attempt to take his life. The principle, in all cases, is that the counter violence must be only so much as is necessary for defence.—The old rule of the law that any who was guilty of a felony deserved death, probably founded the rule that it is justifiable to kill any one who is attempting to commit a felony, such for example as murder, mayhem, or rape. This rule is generally included in the law of self-defence. A man may also justify any violence done in defence of his wife, child, or servant, and either of these persons may justify violence in behalf of husband, father, or master.

SELINUS, the most westerly of the ancient Greek colonies on the S. W. coast of Sicily, at the mouth of the Selinus (now Madiuni) river. It was founded in the 7th century B. C., de-

stroyed by the Carthaginians in 409 and rebuilt, but decayed after the removal of the inhabitants to Lilybæum in 249. The ruins of the city of Selinus (now known as Selinunte and also as Madiuni) are 47 m. S. W. of Palermo, with vestiges of temples, one of which was dedicated to Heron, as shown by an inscription discovered in 1865. The largest were those on the hill E. of the city, outside the walls. One of these, with 8 columns in front and 17 on the sides, 359 ft. long and 162 ft. wide, is described in Swinburne's "Travels" (2 vols., 1777) as one of the most gigantic and sublime ruins imaginable. A new temple with many relics was discovered in 1874 by the architect Carellari, who continued his excavation in 1875. There is a fine collection of sculptured Selinuntine marbles in the museum of Palermo.—See *Selinus und sein Gebiet*, by Reinganum (Leipsic, 1827), and *Die Metopen von Selinunt*, by Benndorf (Berlin, 1873).

SELJUKS, or **Seljuks**, a Turco-Tartaric tribe, of the Uguric division of the race, originally inhabiting the plain N. of the Caspian sea. They received their name from Seljuk, one of their chiefs, under whose guidance in the 10th century they settled in Bokhara, and embraced Mohammedanism. His grandson Toghrul Beg received the title of sultan, conquered successively Khorasan and other Persian provinces, and in 1055 made himself master of Bagdad, which he occupied nominally as the servant and guardian of the caliph, but really with sovereign power, under the title of *emir el-omra* or "commander of the faithful." He died in 1063, and was succeeded by his nephew Alp Arslan, famous for his victories over Romanus Diogenes. (See **ALP ARSLAN**.) He was succeeded in 1072 by his son Malek Shah, who made Ispahan his capital, and extended his dominions from the frontiers of China to the neighborhood of Constantinople. The ill treatment of the Christian pilgrims to Jerusalem by his viceroys was the immediate cause of the crusades. On his death in 1092 the succession to the throne was disputed by his brother and his four sons, and a series of civil wars ensued, which ended in the partition of the Seljukian empire among four branches of the imperial family, of which the principal dynasty ruled in Persia, and the three younger dynasties at Kerman, Damascus, and Iconium. The last named, whose kingdom was called by the orientals the sultanate of Roum (that is, of the Romans), outlasted the others, enduring till the end of the 13th century, when it was succeeded by that of the Ottomans. During the greater part of the 13th century the Seljukian sultans were tributary to the Mongol emperors, who deposed and put them to death at pleasure.

SELKIRK, **Alexander**, a Scottish seaman, born at Largo, Fifeshire, about 1676, died on board H. B. M. ship Weymouth in 1723. He went from England in 1703 as sailing master of the privateer Cinque Ports, and in September,

1704, in consequence of a quarrel with his captain, was put ashore at his own request on the island of Juan Fernandez, which was then much frequented by vessels navigating the Pacific. He was supplied with clothes, arms, ammunition, and other necessities, and remained on the island in solitude four years and four months, when he was taken off by Capt. Woodes Rogers of the privateer *The Duke*, Feb. 12, 1709, and carried to England, where he arrived Oct. 1, 1711. He returned to Largo, but after some time eloped with a girl, whom he married, and went to London. Subsequently he entered the navy, and was lieutenant when he died. Capt. Rogers, in his narrative of his cruise (London, 1712), gave an account of Selkirk's residence on Juan Fernandez; and John Howell published "Life and Adventures of Alexander Selkirk" (Edinburgh, 1829). (See DEFOE, and JUAN FERNANDEZ.)

SELKIRKSHIRE, a S. county of Scotland, bordering on the counties of Edinburgh, Roxburgh, Dumfries, and Peebles; area, 260 sq. m.; pop. in 1871, 14,005. The surface is generally hilly, the hills varying from a few hundred feet in height to about 2,300. The principal rivers are the Tweed and its tributaries, the Yarrow and Ettrick; and there are several small lakes, that of St. Mary's being the finest sheet of water in the south of Scotland. Only about one tenth of the surface is arable.

—**SELKIRK**, the capital, is on the Ettrick, 2 m. from its mouth in the Tweed, 30 m. S. S. E. of Edinburgh; pop. in 1871, 4,640. It has a fine town hall, a monument to Sir Walter Scott, whose seat of Abbotsford is 4 m. distant, and manufactures of wool. Its formerly celebrated manufacture of shoes has declined. The only other town is Galashiels.

SELMA, a city of Alabama, capital of Dallas co., on the right bank of the Alabama river, 95 m. below Montgomery by the course of the river, and about 44 m. W. in a direct line; pop. in 1870, 6,484, of whom 3,660 were colored (by a more recent census, 8,112). In very dry seasons it is at the head of steamboat navigation. It stands on an elevated plateau, which terminates abruptly in a steep bluff forming the bank of the river. Six railroads converge at Selma: the Selma, Rome, and Dalton, the Alabama Central, the Western, the Selma and Gulf, the New Orleans and Selma, and the Selma, Marion, and Memphis. The last three are only partially constructed, and work upon them has been suspended. It has two banks, a cotton factory, an oil mill, a sash and blind factory, a car-wheel factory, three railroad and machine shops, a planing mill, a steam cotton press, six cotton warehouses, and three grist mills. Two daily and three weekly newspapers are published. There are 13 churches, viz.: 3 Presbyterian, 3 Methodist, 2 Baptist, 2 Protestant Episcopal, 1 Cumberland Presbyterian, 1 Congregationalist, and 1 Roman Catholic. There are two public and five private schools. —Selma was an important military and naval

depot of the confederate government during the civil war. An arsenal, a navy yard, nitre works, and foundries for shot and shell were established, giving employment to about 1,800 men. The place was strongly fortified, but the works were carried by assault by the federal forces under Maj. Gen. J. H. Wilson, April 2, 1865, after a short but severe contest with the garrison, under Lieut. Gen. Forrest.

SELTZER WATER (properly **SELTERS**). See **MINERAL SPRINGS**, vol. xi., p. 594.

SELWYN, *George Augustus*, an English clergyman, born in 1809, died April 13, 1878. He was educated at St. John's college, Cambridge, was rector at Windsor for a short time, and was consecrated missionary bishop of New Zealand in 1841, where he labored many years. In 1867 he was appointed bishop of Lichfield. He published "Are Cathedral Institutions Useless?" (1838); "Sermons" (1842); "Tribal Analysis of the Bible" (1855); and "The Work of Christ in the World" (1855).

SEMELE, in Greek mythology, daughter of Cadmus, and sister of Ino, Agave, Autonoe, and Polydorus. She was beloved by Jupiter, and Juno, jealous and indignant, persuaded her to ask him that he would appear to her clothed in the attributes of his majesty. Having sworn to grant her every request she would make, and warned her in vain to desist from this, he unwillingly consented, appeared as the god of thunder, and she was consumed by the lightning; but the child with which she was pregnant was saved by Jupiter, who enclosed him in his own thigh until the period for his birth. This child was Dionysus (Bacchus).

SEMENDRIA (Serb, *Smederevo*), a town of Servia, on the right bank of the Danube, at the confluence of the Yesava, 25 m. E. S. E. of Belgrade; pop. about 5,000. Next to Belgrade it is the most important Servian town and fortress, and it is the see of a Greek archbishop. Good firearms are made here. Formerly it was the capital of the kings of Servia, and it was often taken and retaken by the Turks and Hungarians or Austrians, ultimately remaining in possession of the Turks, who evacuated it in 1867, together with the other fortresses in Servia.

SEMINOLES, a nation of Florida Indians, made up chiefly of two bands of Creeks who withdrew from the main body in 1750 and 1808, and of remnants of tribes partly civilized by the Spaniards, some Mickasuckees, and negroes. They became known as a distinct nation under King Payne. During the American revolution they were under English influence, and very hostile. The Spaniards on recovering Florida made a treaty with the Tallapoosas and Seminoles at Pensacola in May, 1784. The Creeks, who called them Seminoles or Wanderers, still claimed them as part of their nation in the treaty with the United States in 1790. The Seminoles disavowed this claim, and began hostilities against the Americans in 1793, which they renewed in the war

of 1812, although under Spanish rule. They were then divided into seven tribes, and were rich in cattle, horses, and slaves. The war was very destructive to them. Their king Payne was killed in battle at Alachua in 1812, and his brother Bowlegs died soon after. The Creek war led to further trouble between them and the Georgians. In 1817 they surprised settlements on the Saltillo, and cut off Lieut. Scott and 40 persons on the Appalachicola, in revenge for the destruction of one of their forts. Gen. Gaines finally took the field against them, and Gen. Jackson at the head of a large force invaded Florida, and destroyed the Mickasuckee and Suwanee towns, in April, 1818, after hard fighting. The purchase of Florida the next year made them subject to the United States. In 1822 they numbered 3,899, with 800 negroes, in villages from St. Augustine to the Appalachicola, but roaming the whole country. By the treaty of Fort Moultrie, Sept. 18, 1823, the Seminoles gave up all their territory but a small portion, for \$6,000 in goods and a 20 years' annuity of \$5,000; but as Neamathla and other head chiefs refused to join, small reserves were allowed them and their followers by an additional article, Jan. 2, 1824. They also agreed to arrest, hunt up, and deliver fugitive slaves. The enforcement of this led to great trouble. The settlers clamored for the removal of the Indians, and a strange treaty was made at Payne's Landing (1832), by which the Seminoles agreed that if certain commissioners, Indians and others, were satisfied as to the character of the country offered them west of the Mississippi, and the disposition of the Creeks to receive them, the treaty should be binding, and they were to give up all their lands in Florida for \$15,400 and \$3,000 a year for 15 years, but \$7,000 was to be retained for slaves not surrendered. The Seminole delegates were induced to sign a document at Fort Gibson in March, 1833, declaring themselves satisfied. Although they denied having done so understandingly, and the so-called additional treaty did not follow the terms of the original treaty of Payne's Landing, the latter was held to have become absolute, and was ratified by the president and senate in August, 1834. Gen. Thompson, when sent as agent, finding the chiefs opposed to emigration, undertook to depose five, and put Osceola in irons. The Seminoles killed a chief who favored emigration, and then prepared for war. On Dec. 28, 1835, Osceola killed Thompson, a lieutenant, and some others at Fort King, and the same day cut to pieces a body of troops under Major Dade near Wahoo swamp. A long and desolating war ensued, which cost the United States \$10,000,000 and 1,466 lives. The Seminoles met Gen. Clinch on the Withlacoochee, Dec. 31, and subsequently baffled Gen. Scott; but they were so hard pressed by Gen. Call and Gen. Jesup that, after losing several battles, they asked for peace, and in the spring of 1837 agreed to emigrate. Osceola,

however, fled to the woods, and renewed the war. He was defeated by Gen. Taylor in the battle of Okeechobee, and soon after was treacherously seized and kept in confinement till he died. The war was kept up by Coacoochee till he was taken. The prisoners and those who came in were transported to Indian territory, and 1,900 had been removed in 1839. In 1842 those in Florida were reduced to 300, and the war ended. No proper provision was made for the emigrants, and the Creeks wished to absorb them; but a treaty made in 1845 gave them some relief and a separate tract. The negroes among them were claimed by the Creeks or white men, and taken in such numbers that Coacoochee with a large body retired to Mexico. The treaty of Aug. 7, 1856, between the United States, the Creeks, and the Seminoles, recognized them as a nation, and assigned them lands west of the Creeks, which were, however, laid off so incorrectly that they were found to be all within the Creek district. It gave also \$90,000 to the Seminole council, and \$12,500 as an annuity. Of those in Florida, 164 emigrated under Bowlegs in 1858, and the next year, with those who returned from Mexico, their number swelled to 2,253. On the breaking out of the civil war the tribe was divided. The Confederate States made a treaty with them, Aug. 1, 1861, guaranteeing their lands, assuming the obligations of the United States, and agreeing to indemnify them for slaves taken from them by Gen. Gaines. Those who adhered to the government suffered heavy loss in the battle of Dec. 25, 1861, and the survivors retired to Kansas. A treaty was made with the northern and southern bands in December, 1865, by which their old reservation was ceded to government at 15 cents an acre, and a new reservation purchased for them of the Creeks at 50 cents an acre. They then numbered 2,959, including negroes. They are steady, sober, and industrious, and in progress rank next to the Cherokees, Creeks, and Choctaws. Under the treaties of 1856 and March 21, 1866, they receive \$25,000 as an annuity, \$2,500 for schools, and \$1,000 toward the support of the tribal government. In 1874 they had one mission and four district schools; they numbered 2,438, and cultivated 7,600 acres. Their personal property was valued in 1870 at \$237,000. There are still some Seminoles and negroes in Mexico, and 150 or more in the Everglades of Florida. There are also in Texas some 500 negroes formerly slaves to the Seminoles, who returned from Mexico, and in 1875 asked government for lands in Florida or elsewhere.

SEMPOLATINSK. I. A province of Asiatic Russia, in the division of Central Asia, bounded by the governments of Tomsk and Tobolsk, the province of Akmolinsk, Russian Turkistan, and China; area, 188,298 sq. m.; pop. in 1870, 510,163. It comprises part of the country of the Kirghiz, and is divided

into the circles of Semipolatsk, Karkaralinsk, Kokpekty, and Pavlodar. **II.** A fortified town, capital of the province, on the Irtysh, 460 m. S. W. of Tomsk; pop. in 1867, 14,135. It contains several government establishments, and carries on a considerable trade with Bokhara, Tashkend, Kashgar, and the Kirghiz.

SEMIRAMIS, a queen of Assyria, who, according to fabulous traditions handed down by classical authors, reigned about 2000 B. C. Assyriologists suppose that she is the queen Sammuramit, wife of Iva-lush, who lived about 800 B. C. Ctesias, according to Diodorus Siculus, describes her as the daughter of the fish goddess Derceto of Ascalon, and as the wife first of Oannes, and then of Ninus, who died soon after his marriage with her, and left her the sole mistress of the Assyrian empire. She then caused the city of Babylon to be built, encircling it with a wall flanked by many towers and of great height, throwing bridges over the Euphrates, providing it with aqueducts and canals, and erecting in it gorgeous palaces and temples. This done, she made an expedition into Media, Persia, and Armenia, subdued Egypt and the greater part of Ethiopia, and would have conquered India also if her army had not been put to flight by the war elephants of King Stratobatis. Thenceforward she devoted herself entirely to the internal improvement of her empire, and, according to Strabo, in course of time every great work in Asia was popularly attributed to her. Learning that her son Ninyas was plotting against her, she abdicated, left the empire to him, and disappeared as a dove. The real Sammuramit was a queen who had some important works executed at Babylon, but was otherwise of little significance in the political history of the country. It is probable that the accounts of the Greeks are a blending of some of the mythological conceptions of the Babylonians with the facts and popular legends of the early history of the empire.—See F. Lenormant, *La légende de Sémiramis* (Paris, 1874).

SEMITIC RACE AND LANGUAGES. The Semitic race constitutes one of the most important and largest divisions of the Mediterranean or Caucasian type of mankind. (See **ETHNOLOGY**.) The name Semitic (properly Shemitic), first applied by Eichhorn, is in a measure a misnomer, inasmuch as modern ethnology and linguistic science designate by it a much larger family of peoples than are represented in Genesis as descendants of Shem. The inhabitants of Syria and adjoining parts of Mesopotamia, and the coast lands of Palestine, forming the division of North Semites, and the population of Arabia and parts of N. E. Africa, constituting the South Semites, are now grouped together as Semites proper, or Eusemites. Thus the Aramæans (Syrians and Chaldeans), Hebrews, and Phœnicians are North Semites; and the central Arabs or Ishmaelites, South Arabs or Joktanites, and the inhabitants of Ethiopia or Abyssinia, are South Semites.

Furthermore, the term Semitic is made to embrace not only the Phœnicians and Ethiopians, but almost all the large group of peoples usually called Hamites in reference to the Biblical genealogies. The Hamitic Semites, or Dyssemites, include, besides the primitive Assyrians, Babylonians, and Phœnicians, the following three branches: the Egyptian, comprising the ancient Egyptians and the Copts or modern Egyptians; the Libyan, formed by the Berbers and Tuariks (Amazirgh or Imosharh), the Kabyles, Shelloohs, and Guanches; and the Ethiopian, represented by the Bedjas, Bogos, Saho, Agow, Fellatahs or Foolaahs, Galla, Danakil, and Somaali. Lepsius, adopting the opinion of Bleek, the great student of the African languages, includes still another branch, which he calls the South African, and in which he reckons the Hottentots and Bushmen, but of course only from a linguistic point of view. The wide meaning thus given to the term Semitic has been found necessary on account of the almost inextricable interrelationship between the Hamites and the Semites proper. Whether in Mesopotamia, in Palestine, in north Africa, or even in Arabia, the Hamites not only appear as the neighbors of the Semites, but as having generally been ethnologically absorbed by them. The Bible indicates the close relationship existing between Hamites and Semites by representing the Cushites as children of Ham, and the Canaanites as descendants of Cush, and repeatedly applying the name Cush to peoples closely connected with Semites proper. (See **CUSH**.) The enormous gaps between the historical beginnings of the various divisions of the Hamito-Semitic family render futile every attempt to trace a line of migration connecting them all, or to place their common cradle in any one portion of the globe. To ascertain the original physical type of the race, anthropologists turn to the pictorial representations on Egyptian monuments, and examine the proportions of mummies. They were of medium height, the skin reddish yellow, head and face oval, hair dark and curly; the nose was set so as to continue almost in a straight line the massive forehead, and, though often gently turned at the extremity, was never thick and flat. The skeletons of mummies have always exhibited the same proportions as those of the rest of the Caucasian or Mediterranean race. This early type, in which the characteristics of the Hamites are supposed to preponderate, becomes gradually modified from age to age, until the monuments and mummies of a more recent date show those forms and facial outlines which are to this day the distinguishing features of Semites proper, namely: a long face; a medium broad and high forehead; a protruding and strongly bent nose; deep set, vivid eyes, underneath black and heavy brows; undulating, curly hair and beard of brilliant black; the color of the skin of all shades between white, yellow, and brown; well devel-

oped muscles, and symmetrical extremities. It is generally assumed that there is a marked difference between the intellectual development of the Hamites and Semites proper. If the Egyptians, Assyrians and Babylonians, and Phœnicians are essentially Hamitic, the Semites must be considered inferior to them. The Hamites were rather an agricultural race. They early organized into states and empires, and centralized the executive power. They erected colossal monuments and edifices, like the pyramids of Egypt and the palaces of Assyria. Their minds had essentially an objective tendency, and their materialism found utterance in the lascivious religious rites of the Babylonians, and in the strange views and worship of the people of the Nile. Their literature was principally historical, though recent Assyrian and Egyptian discoveries have also brought to light literary productions in other arts and sciences. The peoples designated as Semites proper were generally nomadic. They consisted of independent tribes, which united under some form of patriarchal government. They lived in tents, and had but little taste for architecture and other plastic arts. The Hebrews and Arabs, however, have displayed a peculiar versatility of mind, which allowed them to build up states in various forms, adapt the arts and sciences of other nations, develop extensive literatures, and produce the foremost religions of the world. Monotheism prevails in the religious conceptions of the Semites proper, and the lyric element in their poetry. To the Hamito-Semitic peoples the civilized world is indebted also for the art of writing. The Greeks borrowed their alphabet from the Phœnicians, who imitated the hieroglyphs of the Egyptians. (See WRITING.)—LANGUAGES. No comparative grammar of the Semitic languages proper, or of the Hamitic group alone, much less of the entire Hamito-Semitic family, has been written, and hence it is not fully established in what their common linguistic property consists. There are many minor treatises on special branches of Semitic comparative philology, but no one has even attempted to sum up the general results so far reached, which are very meagre. The opinion that the Assyro-Babylonian language of the cuneiform inscriptions is the Sanskrit of the Semitic family, rests on a very insecure foundation of philological facts. It cannot be denied that the Canaanite group of peoples, Hebrews and Phœnicians, spoke languages much akin to Babylonian; Aramaic manifests a similar relationship by the prevalence of reflexive formations, the want of an article, the transcription of the genitive by a relative pronoun, and by the assimilation of the nasal in *nun* verbs. But on the other hand it is much more consistent with the principles applied to the Indo-European family to allow the claim of priority to the Arabic language, and to consider the other Semitic tongues as shortened or shrunken forms of it, or as having pro-

ceeded from a primordial language of which Arabic is now the representative. The mutual connection of the Semitic idioms proper is very close, so much so that they seem to be dialects of a single tongue, and the differences between them are no greater than between the subdivisions of any branch of the Indo-European family. Ordinarily the type of Semitic speech is spoken of as being inflective like the Indo-European languages; but it does not necessarily follow that both families are of one origin, even if the system of inflection in Semitic were much more like the Aryan than it is. What is above all characteristic of the Semitic languages is the trilateralism of the roots, which in Indo-European tongues are always monosyllabic. Then again, while Indo-European roots are vocalic in form, the Semitic are consonantal. In Semitic the vowel is subordinate, and changeable in inflection, while the consonant is not. The vowel determines only the manner or form of the idea or thing conceived; the idea itself can only be represented by consonants. There is sometimes a semblance of a vocalic root, but there is none such in fact. There are many reasons for concluding that the roots originally numbered only two consonants, and that the triliters and pluriliters are subsequent developments. According to E. Meier, the third radical consonant must be regarded as a reduplication of the originally monosyllabic root, and he has undertaken in his *Hebräisches Wurzelwörterbuch* to analyze the entire root matter of the Hebrew verbs, and to reduce the triliters to radicals of two consonants only. In the opinion of many Semitic scholars, however, his theory is an illusion. The fact that all the Semitic phonetical graphic systems, among which the Egyptian hieroglyphs and the Assyrian cuneiforms are not included, are composed of consonants only, is of great significance. Some of them have a larger number of letters than the Phœnician alphabet from which they are derived, but the nature of the sounds and the manner of uttering them remain the same, and the additional ones are only reduplicated forms of them. Though the graphic systems are of the same origin, and are of a distinctive character constituting them a separate family among the methods of writing, yet they may be subdivided into two groups: one consisting of the primitive Hebrew and Samaritan, and called the Hebrew-Samaritan group; the other comprising Palmyrene, Pamphylian, the square Hebrew characters, Estranghelo and the other Syriac alphabets, the Sabæan or Mendaitic, the Auranitic, the Nabathean and the Arabic, Cufic, and Neshky, and known as the Aramaean group. While the latter subdivision is a direct descendant from the early Aramaean style of writing, the former is a derivative from the archaic Hebrew of the inscriptions. The line of descent will be easily seen on comparing the following alphabets with those given in the article PHœNICIA, vol. xiii., p. 456:

Names of characters.	Archæic Hebrew.	Palmyrene of 10 B. C.	Modern Hebrew type.	English equivalents.

Besides the vowel modifications influencing the sense of the word itself, the Semitic tongues make a wide use of external formative elements, of prefixes and suffixes, and to a more limited extent also of infixes or inserted letters or syllables. There is a marked difference between the Semitic and the Indo-European verb. While equally distinguishing the singular, dual, and plural numbers, and the first, second, and third persons, and forming in a measure after the same fashion the various personal endings, namely, by adding pronominal elements to the verbal roots, yet the Semitic conception of the order of time is so utterly at variance with the Aryan conception of it as to produce an entirely different system of conjugation. There are in Semitic but two tenses, the one denoting generally completed action, and the other incomplete, but both are capable of expressing in certain circumstances present, past, and future time. Though subjunctive, imperative, and other less important modal forms appear

in conjunction with the imperfect, yet the Semitic languages are almost wholly devoid of genuine modal expressions. In their stead the verb admits of a large number of conjugations, giving to it either a transitive, causal, intensive, iterative, conative, reflexive, or other similar meaning. Every conjugation has special forms of verbal nouns and adjectives, infinitives, and participles. The system of conjugations is not equally developed in all the languages belonging to the Semitic family; but, as may be seen in Arabic, it is possible for a verb to have 15 conjugational forms. With the exception of Arabic, no Semitic language distinguishes case, and in Arabic no other than the nominative, genitive, and accusative is indicated. Otherwise nouns are either masculine or feminine, and admit of singular, plural, and dual number.

SEMLER, Johann Salemo, a German theologian, born in Saalfeld, Dec. 18, 1725, died in Halle, March 14, 1791. He studied at Halle, and in 1750 became editor of the *Coburger Zeitung*, in 1751 professor of history at Altdorf, and in 1752 professor of theology at Halle, where he was made director of the theological seminary in 1757. He was at first a pietist, but became a leader of the rationalists. He distinguished between the canonicity and inspiration of the Scriptures, maintaining that they are divine only so far as their contents are of an ethical nature, that the sacred writers "accommodated" their expressions to the mistaken ideas of their times, and that a just criticism can retain the divine element while rejecting what is accommodated and false. He was however an earnest opponent of deism. His works include *Selecta Capita Historiæ Ecclesiasticæ* (3 vols., 1767-'9); *Commentationes Historiæ de Antiquo Christianorum Statu* (2 vols., 1771-'2); *Abhandlung von der Untersuchung des Kanons* (4 vols., 1771-'5); *Apparatus ad liberalem Veteris Testamenti Interpretationem* (1773); *Institutio ad Doctrinam Christianam* (1774); *Versuch einer biblischen Dämonologie* (1776); *Versuch christlicher Jahrbücher* (2 vols., 1783-'6); and *Observationes Novæ, quibus Historia Christianorum usque ad Constantinum Magnum illustratur* (1784). He also published an autobiography (2 vols., 1781-'2).

SEMLIN (Slavonian, *Zemun*; Hun. *Zimony*), a town of the Hungarian kingdom, in Slavonia (formerly in the Military Frontier), at the junction of the Save with the Danube, 3 m. N. W. of Belgrade in Serbia; pop. in 1870, 8,915, mostly Slavonians, Serbs, Germans, and Jews. It is the principal entrepot of the trade between Austria and Turkey. During the Hungarian and Austrian wars with the Turks its situation often gave it importance.

SEMMERING, or **Sömmering**, a branch of the Noric chain of Alps, between Austria proper and Styria, 4,416 ft. high, containing the principal pass between Lower Austria and the more southern provinces of the Austrian empire. In the 14th century a duke of Styria

founded a hospital for travellers on the Styrian side of the pass. A post and carriage road over the mountain was completed by the emperor Charles VI. in 1728; it rises, partly by zigzags, upward of 3,000 ft. above the sea. A new highway, longer, but more practicable, was completed in 1840. A railway over the Semmering, projected and undertaken by a private company, was executed for the Austrian government by the engineer Carlo Chèga between 1848 and 1854. It extends 25 m. from Gloggnitz, at the N. extremity of the pass, to Mürzzuschlag, at the S. extremity. It rises from Gloggnitz, crossing the Schwarzer on a curved viaduct of 13 arches, and sweeping along the shoulders of the hills through a series of magnificent engineering works, including 15 tunnels and 15 bridges, till it attains a height of 2,893 ft. above the sea, when any further ascent is avoided by a tunnel nearly a mile long.

SEMMES, Raphael, an American naval officer, born in Charles co., Md., Sept. 27, 1809, died at Point Clear, Ala., Aug. 30, 1877. He entered the navy in 1826, became lieutenant in 1837, and commander in 1855. In 1834, while awaiting orders, he studied law and was admitted to the bar at Cumberland, Md. During the Mexican war he served both on board ship and as an aide to Gen. Worth. On the outbreak of the civil war he resigned the secretaryship of the lighthouse board at Washington, took command of the confederate steamer Sumter at New Orleans, ran the blockade at the mouth of the Mississippi, and in July, 1861, captured several American merchant vessels in the gulf. He then went to Southampton, England, where he was for some time closely watched by the United States steamer Tuscarora. When he put to sea, the Tuscarora was detained 24 hours by the British authorities; but she followed him to the straits of Gibraltar, and so closely blockaded him in the port of Tangier, that he sold his vessel and returned to England. In August, 1862, he took command of the steamer Alabama, built for him at Birkenhead, England, and manned by an English crew, and continued his career of capturing and destroying merchant vessels. On Jan. 11, 1863, off Galveston, Texas, he engaged the United States gunboat Hatteras, and after a short action sunk her. On June 19, 1864, in an engagement 9 m. off the harbor of Cherbourg, France, the United States steamer Kearsarge, Capt. Winslow, sunk the Alabama. Semmes was taken up by the English yacht Deerhound and carried to England. After the close of the war he entered upon the practice of law in Mobile, Ala. He was arrested and taken to Washington in December, 1865, but was only imprisoned four months. He afterward delivered public lectures on his exploits. He published "Service Afloat and Ashore during the Mexican War" (1851); "Campaign of Gen. Scott in the Valley of Mexico" (1852); "The Cruise of the Alabama and the Sum-

ter" (London and New York, 1864); and "Memoirs of Service Afloat during the War between the States" (8vo, Baltimore, 1869).

SEMPACH, a town of Switzerland, on the lake of the same name, in the canton and 10 m. N. W. of the city of Lucerne; pop. in 1870, 1,109. It is celebrated for a battle fought July 9, 1836, in which 1,300 Swiss vanquished a large Austrian army, through the heroic self-sacrifice of Arnold of Winkelried. (See WINKELRIED.) The Austrian duke Leopold and 1,400 of his knights, with thousands of his foot followers, were slain. A chapel marks the site of the battle field.—See *Die Quellen zur Sempacher Schlacht und die Winkelried-Sage*, by Otto Kleissner (Göttingen, 1873).

SEMPER. I. Gottfried, a German architect, born in Hamburg in 1804. He completed his studies in Italy and Greece, and was professor at the academy of art in Dresden and at the school of architecture from 1834 to 1849, when, being implicated in revolutionary movements, he fled to London. Here he taught at the royal academy till 1856, when he became connected with the polytechnic institute at Zürich. His principal works are the observatory at Zürich, the Festtheater at Munich, new theatres at Dresden and Darmstadt, and the new museum and the new imperial palace in Vienna. He has published *Die vier Elemente der Baukunst* (1851), *Wissenschaft, Industrie und Kunst* (1852), and *Der Styl in den technischen und tektonischen Künsten* (2 vols., 1860-'65).—His son **HANS**, born in Dresden in 1845, and since 1871 professor of German in Rome, has published *Uebersicht der Geschichte der toscanischen Sculptur bis gegen das Ende des 14. Jahrhunderts* (1869), and *Donatello, seine Zeit und seine Schule* (1870 et seq.). **II. Karl**, a German traveller, nephew of the preceding, born in Altona, July 6, 1832. He explored the Philippine islands, and in 1868 became professor of zoölogy at Würzburg. He has published *Reisen im Archipel der Philippinen* (3 vols., 1867-'72); *Die Philippinen und ihre Bewohner* (1869); and *Die Palau-Inseln im Stillen Ocean* (1873).

SEMPLE, Robert Baylor, an American clergyman, born at Rose Mount, King and Queen co., Va., Jan. 20, 1769, died at Fredericksburg, Va., Dec. 25, 1831. He studied theology, became in 1790 pastor of the Bruington Baptist church, and took a leading part in the educational and missionary operations of his denomination, and in the colonization society. In 1820 he was elected president of the Baptist triennial convention, and held the office till his death. In 1827 he became the financial agent of Columbian college, D. C., retaining his pastorate. He published a catechism; a "History of Virginia Baptists," with several biographical notices appended (1810); a "Memoir of Elder Straughan;" and "Letters to Alexander Campbell."

SENAC. I. Jean Baptiste, a French physician, born near Lombez, Gascony, in 1693, died in

Paris, Dec. 20, 1770. He became physician to Marshal Saxe in 1745, and accompanied him through his campaigns. In 1752 he was appointed first physician to Louis XV., by whom he was subsequently made a councillor of state and superintendent general of the mineral waters of the kingdom. His principal work is a *Traité de la structure du cœur* (2 vols. 4to, 1748-'9; new ed., enlarged by Portal, 1774).

II. Gabriel Senac de Meilhan, son of the preceding, born in Paris in 1736, died in Vienna, April 5, 1803. He held various important public offices, and published several works, the best of which is *Le gouvernement, les mœurs et les conditions en France avant la révolution* (latest edition, with introduction and notes by H. de Lescure, Paris, 1862).

SENATE (Lat. *senatus*, an assembly of elders), the deliberative assembly of the Roman people. It was composed originally of 100 members, each representing one of the *decurie* into which the *populus Romanus*, or body of the Roman citizens, when it comprehended but a single tribe, the Ramnenses, was divided. When the Sabines or Titienses were incorporated with the Ramnenses as a second tribe, an equal number of senators was added; and on the admission of the third tribe, the Luceres or Lucerenses, in the reign of Tarquinius Priscus (according to the opinion of recent critics), the number was increased to 300. The new senators were distinguished from those of the two earlier tribes (who were called *patres majorum gentium*) by the title of *patres minorum gentium*. The number was diminished considerably during the reign of Tarquin the Proud, but at the formation of the republic was recruited to the established standard from the principal plebeians of the equestrian order, who were thence called *conscripti*, and it was thereafter customary to address the whole senate as *patres conscripti*, that is, *patres et conscripti*. No permanent change seems to have been made in the number of the senators until the time of Sulla, when it was increased to about 600 by the addition of about 300 *equites*. Julius Cæsar created several hundred new senators, and during the second triumvirate the number exceeded 1,000. Augustus reduced it to 600. The senators held office for life, and were originally men of advanced age; but under Augustus they were admitted in their 25th year. They were elected during the kingly period by the *decurie*, under the republic by the consuls and consular tribunes, and after the establishment of the censorship by the censors exclusively. The persons eligible to fill vacancies were those who had been questors or curule magistrates, and the latter held seats *ex officio*, and were entitled to speak but not to vote. The plebeians as an order were never eligible, but after the questorship and curule magistracies were opened to them, they of course frequently attained to the senatorial dignity. Hence the senate became gradually the real repre-

sentative of the people. No property qualification seems to have been required previous to the time of Augustus, who established a senatorial census, which was increased from 400,000 sesterces to 1,200,000; and any senator falling short of this amount was obliged to withdraw from office. Senators were forbidden to engage in mercantile pursuits, and no one was eligible to office whose parents were not of free birth; but from both these requirements there appear to have been frequent deviations. The senate met on the kalends, nones, and ides of each month during the republic, and under Augustus on the kalends and ides only; but extraordinary meetings could be convoked on any day not a *dies comitalis* or a *dies ater*, by a variety of magistrates, who on such occasions exercised the privilege of presiding. At regular meetings under the empire one of the consuls, or the emperor if a consul, generally presided; and the number of senators constituting a quorum seems to have varied from about 70 to 400. The title of *princeps senatus*, which was originally associated with that of *custos urbis*, and conferred the power of convoking and presiding over the senate, became after the overthrow of the republic purely honorary, and was usually borne by the emperors. After the time of Julius Cæsar the proceedings were regularly recorded by scribes appointed for the purpose. The powers of the senate during the republic comprehended the general care of the public welfare, the superintendence of all matters of religion, the management of all affairs with foreign nations, and the disposition of the finances requisite for these purposes. Its enactments, called *senatus consulta*, which were passed by a majority of votes, under Augustus and his successors took the place of the *leges* enacted by the *comitia tributa*. Its authority was considerably impaired after the institution of the tribunes of the people, and in the latter part of the republic it frequently became merely an instrument in the hands of ambitious generals. The establishment of the empire reduced it to a condition of purely subordinate power, whose functions and very existence were dependent on the will of the emperor; but as a high court of justice it still possessed a considerable degree of importance. A second senate was established by Constantine at Byzantium, upon which Julian conferred powers similar to those of the Roman senate. The latter body continued in existence until the Gothic conquest of Italy, and seems to have been the last depository of what remained of the old national spirit.—The affairs of the Italian cities and provincial towns of the Roman empire were administered by bodies called senates, whose functions were generally civic; and the term is frequently employed in modern times to designate the upper house of the legislature in republican or limited monarchical governments. The senate of the United States is composed of two members for

each state of the Union, who are elected by the legislatures of the states and hold office for six years. In addition to its legislative functions, it has the power of ratifying foreign treaties and nominations to office made by the president, and is the high court of impeachment for public functionaries. Each state of the Union has a legislative chamber which exercises functions of a similar nature, though differing in degree.—The French senate, called the *sénat conservateur*, came into existence after the revolution of the 18th Brumaire (1799), and was originally composed of 80 members of at least 40 years of age. Its chief functions were to prevent violations of the constitution, to introduce changes into that instrument, and to elect the consuls, tribunes, and members of the legislature from lists prepared by the departments. It soon became a tool in the hands of the first consul, and on the establishment of the empire was reduced to the condition of a state council. It was replaced by the chamber of peers at the restoration of the Bourbons, but was revived by Napoleon III. in 1852. This senate was abolished by the revolution of Sept. 4, 1870. In the present French republic, as constituted by the organic laws of Feb. 25, 1875, the senate is to consist of 300 members, 225 elected by the departments, and 75 appointed for life by the national assembly.—The Hanseatic towns are governed by senates, and similar bodies, having legislative functions of various degrees of importance, are recognized by the constitutions of Belgium, Denmark, Italy, and some other European governments. The Russian senate is the supreme judicial tribunal of the empire, and its decrees, when not vetoed by the emperor, have the force of law. In many countries of Europe, particularly in Germany, the affairs of universities are administered by academic senates, composed of the professors, over which the government exercises a control.

SENECA. I. A W. central county of New York, bounded E. by Cayuga lake and Seneca river and W. chiefly by Seneca lake, and drained by the Seneca and Clyde rivers; area, 330 sq. m.; pop. in 1870, 27,823. The surface is hilly and the soil generally very fertile. The New York Central and the Geneva, Ithaca, and Athens railroads, and the Erie and the Cayuga and Seneca canals, traverse it. The chief productions in 1870 were 542,407 bushels of wheat, 420,366 of Indian corn, 627,190 of oats, 409,340 of barley, 22,995 of buckwheat, 182,704 of potatoes, 37,048 tons of hay, 166,416 lbs. of wool, 812,811 of butter, and 100,901 of flax. There were 8,314 horses, 7,073 milch cows, 6,422 other cattle, 28,663 sheep, and 6,997 swine; 17 manufactories of carriages and wagons, 3 of fire engines, 7 of iron castings, 2 of machinery, 7 of malt, 12 of saddlery and harness, 2 of wooden ware, 3 of woollen goods, 9 brick yards, 4 tanneries, 2 distilleries, 12 flour mills, and 15 saw mills. Capitals, Ovid and Waterloo. II. A N. coun-

ty of Ohio, intersected by Sandusky river and Honey and Green creeks, and traversed by several railroads; area, 540 sq. m.; pop. in 1870, 30,827. The surface is almost level, well timbered, and very fertile. The chief productions in 1873 were 621,176 bushels of wheat, 900,915 of Indian corn, 386,564 of oats, 77,232 of potatoes, 484,844 of apples, 34,712 tons of hay, 339,966 lbs. of wool, and 708,252 of butter. In 1874 there were 11,226 horses, 23,091 cattle, 75,914 sheep, and 28,644 swine. In 1870 there were 14 manufactories of agricultural implements, 4 of brick, 12 of carriages and wagons, 6 of iron castings, 1 of woollen, 3 breweries, 7 flour mills, 17 saw mills, 3 planing mills, and 7 tanneries. Capital, Tiffin.

SENECA. I. **Marcus Annaeus**, a Roman rhetorician, born in Corduba (Cordova), Spain, about 61 B. C., died in Italy probably about A. D. 35. He was a member of the equestrian order, and appears to have spent part of his early life in Rome, but afterward returned to Spain, and there married. It is said that he compiled at the request of his children the brilliant and famous sayings which he himself had heard from the rhetoricians of his time. This work was entitled *Oratorum et Rhetorum Sententia*, &c., and consisted of two divisions, one called *Controversiæ*, the other *Suasoria*, only fragments of which are extant. See Koerber, *Ueber den Rhetor Seneca und die Römische Rhetorik seiner Zeit* (Cassel, 1864). II. **Lucius Annaeus**, a Roman stoic philosopher, son of the preceding, born in Corduba a few years before the Christian era, died in Rome, A. D. 65. He studied rhetoric and philosophy in Rome, travelled in Greece and Egypt, and became an advocate, and subsequently quæstor. Messalina, the wife of the emperor Claudius, having accused him of adultery with Julia, the emperor's niece, he was banished to Corsica for eight years, during which he wrote one of his best treatises, the *Consolatio ad Helvium*, addressed to his mother, and the *Consolatio ad Polybium*, to a powerful freedman of Claudius. The authenticity of the latter has been doubted. In A. D. 49, through the influence of Agrippina, who after the death of Messalina had married her uncle Claudius, Seneca was recalled, and was made prætor. Subsequently, with Afranius Burrhus, he became tutor to the young Domitian, the future emperor Nero. After Claudius had been poisoned by his wife, Nero ascended the throne, and Burrhus and Seneca placed themselves in opposition to the pretensions of Agrippina. Not long afterward Nero put his mother to death for her opposition to Poppea, fled to Naples, and sent to the senate a letter written by Seneca, in which he charged Agrippina with a conspiracy against himself, and with having committed suicide in consequence of its failure. In 63 Burrhus died, and Seneca, conscious that the emperor coveted his wealth, offered to surrender his property and retire. This the emperor refused, and from

this period, says Tacitus, Seneca "kept no more levees, declined the usual civilities which had been paid to him, and under pretence of indisposition avoided appearing in public." It is said that Nero tried to poison him, and soon afterward he was accused of complicity in the conspiracy of Piso, and ordered to commit suicide. Without showing any sign of alarm, Seneca had the veins of his arms opened; but as he was thin from age and meagre diet, the blood flowed slowly, and the veins in his legs were also opened. As he suffered excessively, a dose of hemlock was given, but without producing any effect. He was then placed in a warm bath and afterward taken into a vapor stove and suffocated. His wife, Paulina, caused her own veins to be opened, but by order of Nero they were tied up by her attendants, and she lived a few years longer. Besides the two treatises already mentioned, Seneca wrote *De Ira*; *De Consolatione ad Marcianum*; *De Providentia*; *De Animi Tranquillitate*; *De Constantia Sapientis*; *De Clementia ad Neronem*; *Cesarem*; *De Brevitate Vitæ ad Paulinum*; *De Vita Beata ad Gallionem*, to which is sometimes added *De Otio aut Secessu Sapientis*; *De Beneficiis*; 124 *Epistolæ ad Lucilium*, containing moral maxims and observations; *Apocolocyntosis*, a satire on the emperor Claudius; and *Questionum Naturalium Libri VII.* Several other works by Seneca are now lost. Ten tragedies are attributed to him, but their authenticity has been denied: *Hercules Furens*, *Thyestes*, *Thebais* or *Phœnix*, *Hippolytus* or *Phædra*, *Edipus*, *Troades* or *Hecuba*, *Medea*, *Agamemnon*, *Hercules Cæteus*, and *Octavia*. The character and the works of Seneca have been the subject of much controversy. Though a stoic philosopher, he was charged by a contemporary with having amassed an immense fortune by extortion. He was no believer in the superstitions of his country, and has been called an atheist; but his religion appears to have been pure deism. On the other hand, it has been asserted that he was a Christian, and was acquainted with St. Paul; and 14 spurious letters purporting to be written by him to that apostle were printed in the old editions of his works. The *editio princeps* of Seneca is that of Naples (fol., 1475). Of the numerous later editions, that of Schröder (4to, Delft, 1728), the Bipont edition (Strasburg, 1809), and that of F. H. Bothe (2 vols. 8vo, Leipzig, 1819) are valuable. There have been several translations into English.

SENECA FALLS, a village of Seneca co., New York, on the outlet of Seneca lake, the Cayuga and Seneca canal, and the New York Central railroad, 160 m. W. by N. of Albany; pop. in 1870, 5,890; in 1875, 6,125. It has abundant water power and a variety of manufactures. The chief articles produced are steam fire engines, woollens, pumps, flour, machinery, and farming utensils. There are two national banks, an academy, two weekly newspapers, and seven churches.

SENECA LAKE, a narrow sheet of water, lying nearly N. and S. in the W. part of New York, bordered by Seneca, Schuyler, Yates, and Ontario cos. It is about 37 m. long by 2 to 4 m. broad, has an elevation of about 450 ft. above the Atlantic, and about 200 ft. above Lake Ontario, and is surrounded by beautiful scenery. It flows into Lake Ontario through the Seneca and Oswego rivers, and is connected by canals with the Erie canal, with Keuka or Crooked lake near its W. border, and with the Chemung river. It is 630 ft. deep, and was never known to be frozen over till March 22, 1856. It is navigated by steamboats running from Watkins at the S. to Geneva at the N. extremity.

SENECA OIL. See PETROLEUM.

SENECAS, one of the five Iroquois nations in New York, W. of Sodus bay, Seneca lake, and Elmira. They called themselves Tsonnundawago, but received from the Dutch the name of Sinnekaas, which in time became Senecas. They were the hereditary doorkeepers of the cabin, and had eight sachemships, belonging to the Turtle, Snipe, Hawk, Bear, and Wolf families. When first known to the French they were bounded W. by the Attiwandaronk or Neuters on the Niagara, and the Erie S. of Lake Erie. By conquest the Scannonaerats, a nation of the Hurons, most of the Neuters, the Eries, and the Andastes or Susquehannas were successively incorporated with them. Chaumonot began a mission among them in 1657, followed by Fremin in 1668. They permitted La Salle to put up a block house at Niagara; they were afterward hostile, but were won over by Joncaire, and in 1712 permitted the French to build a fort at Niagara. When Pontiac formed his general league of tribes against the English, the Senecas alone of the Six Nations joined him, destroying Venango, attacking Fort Niagara, and cutting off an army train near Devil's Hole in 1763. In the revolution they sided with the English. Gen. Sullivan invaded their country, and, after defeating the allied tribes at Newtown, destroyed several towns, and ravaged the whole canton in 1779. They made peace at Fort Stanwix in 1784. Much of their lands were soon after ceded or yielded to speculators, including the preëmption right of what they still retained. In 1812, though earnestly solicited by their countrymen of the Six Nations in Canada, they formally declared against the English and rendered service to the American armies on the frontier. A part of the tribe settled at Sandusky and Stony Creek, Ohio, joined the hostile tribes in the west, but made peace at Spring Valley in September, 1815. This band ceded all but a reservation with the Shawnees in 1818, and in 1831 sold that and removed to the Indian territory on the Neosho. The Senecas in New York still occupy the Alleghany, Cattaraugus, and Tonawanda reservations (66,000 acres), but white settlers have encroached so that there are thriving towns there. The Senecas in New York in 1870 numbered 3,060; those in the Indian

territory 206. Protestant missions were begun among the Senecas in New York in 1805, and the society of Friends has done much to aid and protect them. Their most illustrious men have been the great orator Red Jacket (see RED JACKET) and Cornplanter. Portions of Scripture have been printed in the Seneca language, and a grammar and dictionary were prepared by the late Rev. Ashur Wright.

SENEFELDER, Aloys, the inventor of lithography, born in Prague, Nov. 6, 1771, died in Munich, Feb. 26, 1834. He was sent to Ingolstadt to study law, and while there occasionally performed in private theatricals, and in 1789 wrote a comedy, *Die Mädchenkenner*. On the death of his father, an actor, he tried unsuccessfully to be an actor and dramatist. Having learned something of printing, he experimented to invent a process of his own, and finally made by accident his great discovery. (See LITHOGRAPHY.) His first prints were some pieces of music. Subsequently he made important improvements, contrived a press, obtained a patent, and set up an establishment, which he carried on for some time successfully. In 1809 he was appointed inspector of the royal lithographing establishment at Munich. He published *Lehrbuch der Lithographie* (Munich, 1819; English translation, "Complete Course of Lithography," 4to, London, 1819).—See *Aloys Senefelder und der geistliche Rath Simon Schmidt*, by Nagler (Munich, 1862).

SENEGAL, a river of Senegambia in western Africa, formed in lat. 14° 10' N., lon. 10° 30' W., by the junction of the Ba-fing and the Ba-Woolima, and flowing thence N. W., W., and S. W. into the Atlantic ocean at Fort St. Louis, in lat. 16° 7' N., lon. 16° 30' W. The Ba-fing, which is regarded as the main stream, rises near Timbo, the principal town of the native state of Fouta Jallon, not far from lat. 10° 30' N., lon. 10° 45' W., in the Kong mountains; and if this be considered as its source, the total length of the river, which is exceedingly tortuous, is about 1,000 m. Between the 13th and 15th meridians, where the Senegal flows westward, it separates into three parallel branches, thus forming two long islands with a stream between them, each over 50 m. long and averaging 6 m. wide. It again becomes double before reaching the sea, into which however it flows as a single stream, 250 yards wide, over a shifting sand bar which will admit vessels of 12 ft. draught. The largest tributary is the Ba-Faleme from the south. The Senegal is navigable for river boats only in the wet season. There is a fall of 80 ft. a few miles below the mouth of the Ba-Woolima.

SENEGAL, an aggregation of French colonial settlements on the Senegal river and its tributary the Faleme, including the island and town of St. Louis at the mouth of the Senegal, and Goree, off Cape Verd; pop. estimated in 1874 at 100,000. The French have here attempted the system of military colonization applied in Algeria, with but limited success; and a con-

siderable portion of the territory claimed and to some extent occupied by them in this region prior to 1870 was abandoned in that year. In 1872 the value of the exports to France was 10,800,000 francs, and of the imports from France 6,400,000 francs, the commerce being almost exclusively in the hands of the French. The establishment is under a colonial governor, with a military and naval force under his command.—French trading posts were established in this region in the early part of the 17th century, and in the 17th and 18th centuries were controlled successively by the West India company, the Senegal companies, and the East India company. The English held them by conquest from 1758 to 1779, and from 1803 to 1814.

SENEGAMBIA, a region of western Africa, formerly comprising only the territory lying between the rivers Senegal and Gambia, from which it derives its name, but now held to include the whole of the country between the former river and the British colony of Sierra Leone. It is bounded N. by the Sahara, E. by Soodan, S. by Sierra Leone, and W. by the Atlantic, and extends from lat. 9° to 17° N., and from about lon. 10° W. to Cape Verd, in lon. 17° 34' W. Its eastern boundary is so indefinite that an accurate estimate of the area is impossible; it can hardly be less than 200,000 sq. m., and has been placed much higher. The population is estimated at 9,000,000. It includes the French colony of Senegal, and French power predominates on the coast and in the country. There are English settlements along the Gambia, of which Bathurst at its mouth is the principal town and the seat of government; and the Portuguese establishments at the mouth of the Rio Grande and in the interior in 1873 embraced a territory of 43 sq. m., with 8,500 inhabitants. The objects of these foreign establishments are purely commercial. The coast region of Senegambia consists of a belt of level land extending inland from 150 to 200 m., which in the north is for the most part open, sandy, low, and barren, with here and there a few rocky cliffs; but S. of the Gambia the aspect of the country changes, the vegetation becomes luxuriant, and the deeply and frequently indented coast is bordered by mangrove swamps, back of which rises a rich forest region. The principal rivers, described under their own titles, are the Senegal and Gambia, S. of which three others of considerable size empty into the Atlantic: the Casamanza or Casamanche, navigable 80 m. from its mouth; the Rio Grande, 400 m. long; and the Nuñez, of about half that length. With the exception of the coast and the alluvial flats along the rivers, the country is undulating, and rises in terraces from the ocean to the mountains of the interior, which overspread the S. E. portion, and attain an elevation variously stated at from 3,000 to 6,000 ft. Little is known of Senegambian geology, except the occurrence of granite in the mountainous region. Iron.

ore is abundant in the elevated districts, and gold is found in large grains lower down. The climate is reputed to be the most continuously hot of any in the world. The highest temperature is experienced in the vicinity of the Sahara, in the north, where the mercury sometimes rises to 110° F. in the shade; on the coast the average is about 80°. Throughout most of the country the rainy season lasts from June to December inclusive, and is characterized by tornadoes at midsummer, with thunder and lightning of tropical intensity. Much of the land is exceedingly fertile. In the forests are found the oil-producing palm and many valuable kinds of timber, gums, and caoutchouc; cardamoms, ground nuts, and cassia are also obtained, and indigo grows wild. Wild coffee also is abundant on the banks of the Nuñez. Rice, maize, and millet are the chief grains cultivated. Hemp is extensively grown. All the domestic animals of Europe are found, in addition to which there are camels in the desert country of the Jaloofs. Large numbers of cattle are raised on the pasture lands of the terraces. Elephants are very numerous, and the hippopotamus is found in all the rivers. Buffalo, deer, a species of eland, antelopes, wild boars, hares, porcupines, lions, panthers, and hyænas are all natives of the country. Crocodiles are numerous, and the boa frequents the marshy grounds.—The inhabitants consist of the aboriginal negro tribes, Moors, and the offspring of these two races, a people of middle size, of a light copper color, well made and active. Many of the women are remarkably handsome, and both sexes dress neatly. They are much more civilized than the black tribes, of which the lower type is found along the coast, while the Mandingoes, the Jaloofs, and others of this mixed descent dwell further inland, and live under regular governments, generally consisting of a king and hereditary nobility. They keep large numbers of slaves. The Mohammedan religion prevails among them. There are about 20 native states in the country. The most important of these is the Foola state of Foota Jallon, with its capital at Timbo, occupying an elevated plateau over 80 m. square, in the south, near the head waters of the Senegal. (See FOOTA JALLON.) The kingdom of Bondoo and the territory of Foota are described under their own titles, as is also the Mandingo country proper, which some include in Senegambia. Besides the trade carried on by the French, English, and Portuguese from their settlements upon the three rivers, which is mainly in palm oil, gum, hides, beeswax, ground nuts, and wild coffee, a considerable traffic exists between Senegambia and the countries lying further E. Much of the gold found in the elevated districts is carried to Timbuctoo, and thence finds its way to the countries N. of the Sahara.—The Carthaginians visited this part of the coast of Africa, and the Portuguese reached it between 1444 and 1469. The latter nation

formed several commercial establishments, but afterward neglected them when they discovered the route to India. The British acquired their possessions on the Gambia in 1631, and the French settled on the Senegal in 1637.

SENIOR, Nassau William, an English political economist, born at Uffington, Berkshire, Sept. 26, 1790, died June 4, 1864. He graduated at Magdalen college, Oxford, in 1811, and was called to the bar in 1819. From 1825 to 1830, and again from 1847 to 1852, he was professor of political economy at Oxford. From 1836 to 1853 he was a master in chancery. His works are: "Introductory Lectures on Political Economy" (1826); "On Foreign Poor Laws and Laborers" (1840); "Treatise on Political Economy" (1850); "A Journal kept in Turkey and Greece in 1857 and 1858" (1859); "American Slavery" (1862); "Biographical Sketches" (1864); "Essays on Fiction" (1864); "Historical and Philosophical Essays" (1865); "Journals, Conversations, and Essays relating to Ireland" (1868); "Journal kept in France and Italy in 1848-'52" (1871); and "Correspondence and Conversations with Alexis de Tocqueville" (1872). (See POLITICAL ECONOMY, vol. xiii., p. 672.)

SENILIS (anc. *Augustomagus*), a town of France, in the department of Oise, near the forests of Chantilly and Ermenonville, 20 m. N. N. E. of Paris; pop. in 1872, 6,085. The old town retains its feudal walls and 16 watch towers, and remains of a castle of the time of Louis XII., as well as vestiges of the Roman fortifications and other relics; and remains of amphitheatres were discovered in 1865. The church of Notre Dame was originally a cathedral, ascribed to Charlemagne. Cotton, crinoline, and other articles are made. The town is conspicuous in the history of various French wars. A treaty was concluded here in 1493 between the future emperor Maximilian and Charles VIII. of France, which settled the Burgundian inheritance.

SENNA (Arab. *sene*), a drug which consists of the dried leaves of several species of *cassia*, of the order *leguminosæ*. In the most familiar plants of this family, as the pea, locust, lupin, and others, the corolla is papilionaceous, and the stamens are united to form a more or less complete tube. In the genus *cassia* and its allies, the corolla is of distinct and spreading petals, with distinct stamens. The cassias which furnish senna are bushy shrubs, 2 to 4 ft. high, with unequally pinnate leaves, the leaflets of which are unequal at the base and in four to eight pairs; the yellow flowers are in erect axillary racemes, and the broad flattened pods contain six or more seeds. *C. acutifolia*, with ovate or lanceolate leaves, and *C. angustifolia*, with narrower and longer leaves, furnish most of the drug, which was in use as early as the 9th century, and still retains its popularity. The principal commercial varieties are the Alexandrian, produced by *C. acutifolia*, and collected in various districts of Nubia; the

Bombay or East Indian, from *C. angustifolia* of southern Arabia and various parts of India; and the Tinnevely, which is merely the last named species cultivated in India; the leaves

Cassia acutifolia. Plant reduced; leaf and pod of natural size.

of this are much larger, as the plant is more luxuriant. The gathering of the first two is done mainly at the close of the rainy season, in September; the bushes are cut and exposed to the sun until the leaves are quite dry, when they are separated by beating with sticks; the whole and broken leaves, the small stems, and the pods are sent to the place of export. Some of it is garbled to remove extraneous matters before it is shipped. Tinnevely senna, being a cultivated product, is collected with more care, and is a very superior variety of the

American Senna (*Cassia Marilandica*).

drug. Senna was formerly much more contaminated by foreign leaves than now; the poisonous *coriaria myrtifolia* of southern Europe was used to adulterate it; in Alexandria

senna argel leaves may be often found, but as this (*sarcostemma argel*) grows with the senna plants, it is supposed to be an accidental admixture. Senna is an active cathartic, and is largely used both by physicians and in domestic practice; it is usually given in infusion, but sometimes in the fluid extract, tincture, and confection. It contains two bitter principles, and a cathartic acid upon which its activity chiefly depends. The active principle is readily changed by long continual heat and exposure to the air; hence the infusion should always be made in a covered vessel.—American senna, or wild senna as it is sometimes called, is *cassia Marilandica*, a perennial herbaceous plant, which grows from New England southward and westward; the root produces numerous erect stems 2 to 4 ft. high, clothed with leaves which have six to nine pairs of lance-oblong, obtuse leaflets, the common petiole bearing at its base a conspicuous club-shaped gland; the bright yellow flowers are in axillary racemes, the two lower petals are the largest, and the anthers of the three upper stamens are deformed and imperfect; the fruit is a narrow, somewhat curved, hairy pod, 3 to 4 in. long. This is a very showy plant, and is now and then seen in gardens, though it is not so well appreciated here as it is in Europe. The leaves are gathered for medicinal use; they possess properties similar to those of the imported senna, but are less active, a third larger dose being required to produce the same effect.

SENNAAR, a country of Africa, forming part of the territory commonly known as Nubia, and now included in the aggregation of Nile provinces constituting the dependency of Egypt officially known as Soodan. It is bounded E. by Abyssinia and W. by Kordofan, and extends S. from the junction of the Blue and White Nile in lat. 15° 36' N. to about lat. 10°, but its boundaries are not well defined; area about 50,000 sq. m.; pop. 1,500,000. It consists chiefly of the peninsular territory lying between the Bahr el-Azrek or Blue Nile on the east and the Bahr el-Abiad or White Nile on the west, with its N. extremity at Khartoom. The chief towns are Khartoom, where the governor resides, Sennaar, the former capital, on the Blue Nile, and Wat Medineh, described by Sir Samuel Baker as the principal trading place on the same river. The country consists of a plain from 1,400 to 1,500 ft. above the sea. There are some isolated summits nearly 1,000 ft. above the surrounding country; and toward the S. boundary the surface becomes very mountainous. The plain of Sennaar rests upon a regular horizontal stratum of sandstone, and the mountains consist of crystalline rocks, clay slate, and limestone; while many of the isolated hills are composed of granite, and some contain veins of auriferous quartz and gneiss. Iron ore is abundant, and salt is found on the White Nile and at Khartoom. The soil of the plain is for the most part a rich black mould, though there are many

sterile and unproductive tracts. Rain seldom falls in the north, sometimes not for two or three years together; but in the south it is abundant between May and September. The climate is exceedingly hot, the thermometer rising to 120° in the shade. Extensive forests border the flat tracts along the White Nile, and in the lower part of the country where the river overflows its banks abundant crops of durra and beans are raised. These are the principal products, but wheat, cotton, and tobacco are also cultivated. Much of the country is well adapted for pasturage, and large numbers of horses, camels, sheep, goats, and cattle are raised. Among the leading exports are leather and cotton goods to the neighboring countries, ivory, ostrich feathers, and honey. The elephant, giraffe, rhinoceros, antelope, lion, leopard, hyæna, baboon, hippopotamus, wild boar, crocodile, heron, and ibis are met with. The inhabitants represent a number of races, and vary from light yellow to black. There are several Arab tribes, and the territory of the Dinkas embraces the S. W. corner of Sennaar. The better classes are generally well made and handsome, but about half the population are negro slaves. The people understand working in metals, and are good weavers and potters, and particularly skilled in leather making, which is their chief manufacture. Cotton stuffs are also made. Mohammedanism is the prevailing religion, but its requirements are little regarded, and there are many Christians and pagans in the S. E. part of the country.—Sennaar formerly belonged to Abyssinia, and was subsequently annexed to the government of Nubia, but appears to have achieved independence about the 14th century. Its history is imperfectly known, but there is reason to believe that during the last 200 years its territory has been parcelled out among various chiefs practically independent of one another. Since the invasion by Ismail Pasha in 1820-'22 Sennaar has been subject to Egypt.

SENNACHERIB. See ASSYRIA, vol. ii., p. 35.

SENS (anc. *Agendicum* or *Civitas Senonum*), a town of France, in the department of Yonne, on the right bank of the Yonne, 60 m. S. E. of Paris; pop. in 1872, 11,514. It is the seat of an archbishop, and has a museum of antiquities, an episcopal seminary, a theatre, and an ancient Gothic cathedral. Serge, druggets, dials, pottery, cutlery, and nails are manufactured.—In the time of Julius Cæsar Sens was one of the principal towns of the Senones, and subsequently as capital of Lugdunensis Quarta it was a focus of great Roman roads. It was strongly fortified and often besieged. It was taken by the allies, Feb. 11, 1814, after a brave resistance by the inhabitants.

SENSITIVE PLANT. See MIMOSA.

SEPIA, a pigment made from the black secretion of the *sepia* or cuttle fish, which it ejects when pursued or annoyed. This secretion was used as an ink by the ancients. Several

varieties of *sepia* yield the ink, but the *sepia officinalis*, common in the Mediterranean, affords the most, and is the one chiefly sought. The sac containing the secretion is extirpated, and the juice dried as soon as possible, as it quickly putrefies. Caustic alkalies render it soluble in water, but absorption of carbonic acid again precipitates the *sepia*. The dried native *sepia* is prepared for the painter by triturating with caustic lye, adding more lye, boiling half an hour, filtering, neutralizing with an acid, filtering, washing the filtrate, and drying it with a gentle heat. It has a beautiful brown color with a fine grain, and has given name to a species of drawing.

SEPOYS (probably from Pers. *sipahi*, a soldier), the native soldiers of the British army in India. The practice of employing the natives as troops originated with the French about the middle of the 18th century, and in 1748 the East India company organized a small body of sepoys at Madras, which had increased to 14 battalions, numbering 10,000 men, at the time of the battle of Plassey. Two of the battalions took part in the expedition under Clive, who at once began to form a similar native army in Bengal, which as early as 1765 contained 19,000 troops. A sepoy force was also raised in Bombay, which consisted of about 3,500 men in 1772; and in 1773, when the office of governor general was established, the estimated strength of the East India company's native army was 45,000 men. This entire military establishment was reorganized in 1796 on a basis which remained essentially unchanged till 1861. A native regiment was about 1,100 strong in Bengal, and 900 in Madras and Bombay; there were about 120 native non-commissioned officers, 20 native commissioned officers, and theoretically 25 European officers, but in fact only 12 or 15. The highest rank to which a native could attain was that of *subahdar* or captain; native lieutenants were known as *jemadars*, and sergeants as *havildars*. The sepoys were volunteer troops. Those of the Bengal army were mainly high-caste Hindoos, but in the armies of Madras and Bombay the aristocratic element was not so prominent. According to Kaye, the Bengal sepoy was to the outward eye the finest soldier, tallest, best formed, and of the noblest presence; but he was less docile and serviceable than the sepoy of the southern and western armies. Notwithstanding occasional local mutinies and murderous outbreaks on the part of the native soldiery, their discipline, fidelity, and good service in the field, extending through so many years, inspired an extraordinary and almost universal confidence in their loyalty, which existed throughout India up to the beginning of the great sepoy revolt in 1857. (See INDIA.) When it began, the East India company's army consisted of about 300,000 men, all sepoys with the exception of 40,000. The mutiny was almost wholly confined to the Bengal army; in Madras but a single regiment was

disaffected, and in Bombay none at all; while the native forces from the Punjaub assisted in repressing the rebellion. Upon the subsequent transfer of the army to the crown, a reorganization became necessary. This was effected in 1861, by a reduction of its numbers one half, the abolition of promotion by seniority, and the permanent appointment of seven effective officers to each regiment. The troops are nominally on the footing of irregulars. There are 137 battalions of infantry, 40 regiments of cavalry, and a few batteries of artillery. The number of men in 1873 was 128,447, of whom 103,343 were infantry.

SEPS (Daud.), a genus of saurian reptiles of the skink family, divided by modern authors into several subgenera. In the group the feet are very short, and have three or four toes, with claws; the apex of the tongue is notched, the eyes lizard-like with transparent lower lid; teeth numerous and conical; body snake-like, and the scales smooth and imbricated; no femoral pores. The four-toed seps (*tetradactylus Decresiensis*, Péron) has the nostrils in the nasal scute, and a conical tail about as long as, and hardly distinct from, the body; the color above is brownish spotted with black, the sides grayish with dark dots, and whitish below; it is about $5\frac{1}{2}$ in. long, the anterior limbs one fourth and the posterior five eighths of an inch; it is found in Australia and the neighboring islands. The three-toed seps (*hemiergis Decresiensis*, Dum. and Bibr.) is distinguished from the last chiefly by the number of the toes, of which the central is the longest; the color and habitat are the same; the length is about 4 in., the anterior limb $\frac{1}{2}$ in., and the posterior about half as long. The common seps (*seps tridactylus*, Merr.) has a

Seps tridactylus.

more elongated body and shorter limbs, and the nostrils are between the nasal and rostral scutes; the feet are three-toed. The color is bronze above, usually with four longitudinal darker stripes, and greenish white below; the number of stripes and the black and white markings vary; the length is 16 in., the anterior limbs $\frac{2}{3}$ in. and the posterior $\frac{1}{2}$ in. It is

viviparous, and is found in southern Europe and northern Africa; the food consists of worms, small land mollusks, spiders, and insects. An allied species (*heteromeles Mauritanicus*, Dum. and Bibr.) of N. Africa has only two toes on the fore feet; it is grayish white dotted with black above, and whitish below; the length is $4\frac{1}{2}$ in., the anterior limbs $\frac{1}{2}$ in. and the posterior $\frac{1}{2}$ in.

SEPTEMBER (Lat. *septem*, seven), the ninth month of the year, but the seventh with the early Romans, their year beginning with March, as the legal year did in England until the change of style in 1752. The name is still retained in most European languages, like those of the three succeeding months, notwithstanding their present inaccuracy. The Anglo-Saxons called it *Gerstmonath*, or barley month; and in Switzerland it is still called *Herbstmonat*, harvest month. It has 30 days.

SEPTIMIUS SEVERUS. See SEVERUS.

SEPTUAGINT. See BIBLE, vol. ii., p. 613.

SEPULVEDA, Juan Ginez de, a Spanish historian, born at Pozoblanco, near Cordova, in 1490, died in 1574. He assisted Cardinal Cajetan at Naples in the revision of the Greek Testament, in 1529 went to Rome, and in 1536 was appointed chaplain and historiographer to Charles V. He wrote a work justifying the wars and acts of the Spaniards in America, which was never printed. He also wrote histories of Charles V. and Philip II. (whose education he had superintended), and a narrative of the Spanish conquests in Mexico. His works have been published by the royal academy of history at Madrid (4 vols. 4to, 1780).

SEQUANA. See SEINE.

SEQUATCHIE, a S. county of Tennessee, intersected by the Sequatchie river, a tributary of the Tennessee; area, about 250 sq. m.; pop. in 1870, 2,335, of whom 175 were colored. The surface is very hilly and the soil moderately productive. The chief productions in 1870 were 12,472 bushels of wheat, 13,010 of Indian corn, 6,905 of oats, 9,353 lbs. of tobacco, and 5,904 of wool. Iron and other valuable minerals abound. Capital, Dunlap.

SEQUIN (Ital. *zecchino*, from *zecca*, the mint), an old Italian and Turkish gold coin. It was first struck at Venice about the end of the 13th century, and afterward in all the other Italian cities, and by the Levant trade introduced into Turkey. The Tuscan sequin is worth \$2.313; the Turkish varies according to the date of coinage.

SEQUOIA, the botanical name of a genus of large coniferous evergreen trees, consisting of but two species, both of which are natives of our Pacific coast. The name was imposed by Endlicher, who left its derivation unexplained, but it has since been maintained that it was given in honor of the Cherokee Sequoyah or George Guess. (See GUESS.) The species first made known was the redwood of the Californians, *S. sempervirens*, which was discovered by Menzies in 1796, and from imperfect

specimens was referred to *taxodium*, the genus of our deciduous cypress. Endlicher found that it did not belong to the cypress subfamily, but that its affinities were with the pines and

Redwood (*Sequoia sempervirens*). Male and Female Flowers.

cedars; its awl-shaped or linear leaves are scattered, or somewhat two-rowed; its flowers monœcious, terminal and solitary; sterile aments globular, on slender stalks; the cones oval or globular with woody shield-shaped scales, beneath each of which are three to seven winged seeds. The redwood has leaves half an inch to an inch long, two-rowed, flat, dark shining green above and glaucous beneath; as is the case with many other conifers, the leaves of the redwood are quite unlike in the young tree, where they are spreading, to those on the older trees, where they are closely appressed. The cones are an inch or more long, roundish, with thick roughish scales, each of which has a strong obtuse point. The tree is found from the boundary of Mexico northward, its northern limits being not well ascertained, and never very far from the coast; upon the Coast range of mountains it often forms forests to the exclusion of all other timber. It sometimes reaches a diameter of 15 ft. and a height of 300 ft.; 1,008 annual rings have been counted upon a slab taken from a tree 15 ft. through. The redwood has been of more value to the settlers in California than perhaps any other tree, the forests being near the ocean, though in many cases they have been found so inaccessible that it was cheaper to purchase lumber brought from Oregon than to transport redwood from the rugged hills only a few miles distant; the timber is light and close-grained, but not very strong; it much resembles in appearance that of the red cedar, but is darker; it splits with remarkable facility, and in some localities has been largely used for fencing; it may be made into planks and boards without the use of a saw; being

eminently durable, and not attacked by insects, it is used for building purposes and for cabinet work; it is said to dry without shrinking.—The second and only other species of *sequoia* is *S. gigantea* (Torrey), popularly known as the "great tree of California," and the "mammoth tree," and the groves of which are generally called "the big trees." This species was first discovered by some miners, who in prospecting came upon what is now known as the Calaveras group; afterward the Mariposa and Fresno groups were discovered, and later Prof. William H. Brewer made known the existence of extensive forests of the tree along the western flanks of the Sierra Nevada. The California botanists early secured specimens of the tree and forwarded them to Drs. Torrey and Gray, proposing, should it prove to be a new genus, to call it *Washingtonia*; the specimens were lost upon the way; about the same time an English collector, Mr. Lobb, sent incomplete materials to England, and Lindley named it as a new genus, *Wellingtonia*. In 1855 Dr. Torrey received very complete materials, and found that the tree belonged to the already established genus *sequoia*, and published it as *S. gigantea*. The English still retain *Wellingtonia* as their name for the tree, and some of their leading botanists, while admitting that the tree is *sequoia*, so far ignore

Mammoth Tree (*Sequoia gigantea*). Leaves reduced, with three of natural size; cone and section, half size.

the rules of nomenclature as to call it *S. Wellingtonia*. Books of California travel have made the trees of this species well known, and until the recent discovery of Australian eucalypti as large if not larger, they were regarded as the most gigantic of vegetable productions; 30 ft. is not an unusual diameter, and some have measured 33 and 36 ft., and with their buttresses even more in diameter, and their heights are estimated at 275 to 450 ft. A striking peculiarity of these trees is the disproportion between the expanse of the foliage

and the size of the trunk. It is now known that the trees grow with astonishing rapidity when young, but after they have reached their maturity (something over 1,000 years) they

Group of Mammoth Trees.

make but little growth. The bark, often 15 in. thick, is of a brown or cinnamon color, and the wood is similar to that of the redwood; when oiled and exposed to the light it becomes of a very deep mahogany color. This species differs from the redwood in its shorter leaves of a light glaucous green, and its larger ovate cones, the scales of which have each a slender prickle. The cultivation of both species has been tried in the eastern states, but without encouraging success; specimens that gave great promise have one after another succumbed either to severe winters or to mildew, and they have both failed entirely, at least north of Virginia. In England they flourish remarkably well, and *S. gigantea* has made a growth remarkable for any tree, and especially rapid for a conifer, and it will probably prove important for planting in forests. (See CALIFORNIA, vol. iii., p. 606.)

SEQUOYAH, an unorganized S. W. county of Kansas, intersected by the Arkansas river; area, 720 sq. m. The surface is elevated, and consists chiefly of rolling prairies.

SERAGLIO. See CONSTANTINOPLE.

SERAING, a village of Belgium, in the province and 3 m. S. W. of the city of Liège, on the right bank of the Meuse; pop. in 1866, 19,414,

against 2,000 in 1820. It has mines of iron and coal, and is the seat of the works established in 1816 by John Cockerill, and now managed by a company, producing locomotives, steamboats, and all kinds of machinery.

SERAMPORE, a town of British India, in the Hoogly district of Bengal, on the W. bank of the Hoogly 13 m. N. of Calcutta, with which it is connected by rail; pop. about 15,000. It extends about a mile along the river, and is well built and clean. Serampore was a colony of Denmark from 1676 to 1845, when it was purchased by the English. The first Baptist mission in Hindostan was established here, and here also was published the first native newspaper, printed by the missionaries from 1818 to 1823. The principal industry of Serampore is the manufacture of paper.

SERAPIS, or **Sarapis**, an Egyptian divinity, whose worship prevailed in the reign of the Ptolemies. The name is supposed to be a compound of Osiris and Apis, or a conversion of the name Osir Hapi given to the dead Apis. The worship of Apis, but little developed in the time of the Pharaohs, became in another form of primary importance under the Ptolemies. According to Plutarch and Tacitus, Ptolemy I., warned by a dream, sent to Sinope for a colossal statue, which on its arrival at Alexandria was declared to represent the god Serapis. The temple Serapeum was built at Alexandria for the reception of the statue, and was the last hold of the pagans in that city after the introduction of Christianity. It was a magnificent structure, supported by arches, and divided within into spacious apartments. It was destroyed by the bishop Theophilus, by order of Theodosius, in 389; and "the colossal statue of Serapis was involved in the ruin of his temple and religion." Canopus was the seat of a shrine and oracle of Serapis. The worship of Serapis prevailed for a short time in Rome in A. D. 146, under Antoninus Pius, but was soon suppressed on account of its licentious character. At Puteoli (Pozzuoli) there was a Serapeum, the ruins of which were uncovered in 1750, and are regarded as among the most remarkable remains of ancient architecture in Italy. In 1850 Mariette discovered the site of the Serapeum or Apis mausoleum at Memphis. It has now been completely unearthed. It is divided into three distinct parts; one served as the burial place of the sacred bulls from Amunoph III. of the 18th dynasty to the end of the 20th dynasty; another comprises the tombs of the Apis until the end of the 25th dynasty; and the third, which is the best preserved, those of the time till the later Ptolemies. Nearly 200 sphinxes have been laid bare, and the inscribed tablets which covered the walls, numbering about 500, have been removed to the Louvre.

SERAYEVO. See BOSNA-SERAI.

SERBATI. See ROSMINI SERBATI.

SERF (Lat. *servus*, a servant or slave), a term descriptive of the condition of a large portion

of the people of Europe in the middle ages and in later times. Slavery and various forms of bondage prevailed throughout the whole of the Roman empire, and slavery was known to some of the races by whom that empire was overthrown; and out of the social and political conflicts produced by the barbarian invasions of the empire arose the feudal system. (See FEUDAL SYSTEM.) The invaders found a portion of the agricultural populations of the countries they acquired in a condition between servitude and freedom. These were the *coloni*, or bond laborers, who were attached to estates. Under the German conquerors of Gaul, where the feudal system experienced its greatest development, and where serfdom became the most extensive and severe in its application to the masses of the people, labor was almost entirely servile and compulsory. Some lords possessed more than 20,000 slaves each. The capitulary *de Villis* shows that the royal farms were cultivated by slaves, and it is estimated that they embraced a fourth part of the land. In time the benefices that were granted became heritable, so that the beneficiary exercised over the slaves not merely the power of an owner, but also that of a magistrate. Montesquieu asserts that at the beginning of the ascendancy of the third dynasty, in the 10th century, nearly all the people of France were serfs. The extreme sufferings of the people from famine compelled many of them to sell themselves into slavery; others exchanged liberty for the protection of powerful men. Offenders against the laws, who could not pay the compositions demanded of them, and persons who had failed to perform their military duties, were made serfs, or were liable to be so made. Some men voluntarily became the property of churches and monasteries. The effect of the barbarian conquests had been on the whole advantageous to the slaves found in the conquered countries, though it had considerably depressed the *coloni*. The two classes of forced laborers had been brought nearer together, the more favored class suffering somewhat from the change, while the less favored class gained a little therefrom. For several centuries this state of things lasted, to the detriment of the *coloni*, or villeins, as they were called by the juriconsults. The effect of the establishment of the feudal system, on the other hand, was beneficial to both the serfs and villeins. Chattel slavery ceased to exist, and they could no longer be bought and sold. This was principally owing to the influence of the church, which denounced traffic in Christians. The serfs became hereditary bondmen, and were employed on the soil, with which they were transferred. The difference between the serfs and the villeins, however, was so faint in many respects that they are generally spoken of as forming one and the same class, even by the highest authorities. But the distinction was real, the villeins holding a medium position between the serfs and the ingenuous classes, or freemen. The serfs, who are some-

times spoken of as a lower class of villeins, were in theory in the most abject state, and practically they often were so. Beaumanoir, after pointing out the two conditions of gentlemen and freemen, says: "The third estate of men is that of such as are not free; and these are not all of one condition, for some are so subject to their lord that he may take all they have, alive or dead, and imprison them whenever he pleases, being accountable to none but God; while others are treated more gently, from whom the lord can take nothing but customary payments, though at their death all they have escheats to him." The former were serfs, the latter villeins. The villein was obliged to remain upon his lord's estate. He could not sell his lands, and his person was bound, and he could be reclaimed and brought back if he left his superior. This was the condition of both serfs and villeins; but the former were bound to the performance of ignoble services, from which the latter were exempt. It was only against his lord that the villein was without rights, at least in England; and "he might inherit, purchase, sue in the courts of law, though, as defendant in a real action or suit wherein land was claimed, he might shelter himself under the plea of villenage." Children generally followed the condition of their mother, but in England the state of the father determined that of the children as far back as the reign of Henry I., the first third of the 12th century. There the law presumed that the fathers of the bastards of female villeins were free, or that bastards were the sons of nobody, and therefore could not be the sons of slaves. In France, the free woman who married a serf was treated as being of her husband's condition; and in Flanders, if a free man married a villein, he became a villein himself after living with her a year. Before the establishment of the feudal system, and under the Carlovingian rule, it had been provided that a free man who had taken a villein to wife could divorce her if he had been deceived as to her condition. Villeins could not marry without their lord's consent, or they forfeited their property, or were fined. The treatment of the servile classes differed much in different countries, and villenage literally disappeared from England long before it was broken up in France. It was never abolished by statute. —In France, the rise of men from a servile condition began very early and continued until great changes were effected. Many of the *coloni* aspired to freedom at the time when the feudal system was in its most flourishing state, and not a few of them were successful in throwing off their bonds. Those on the estates of kings and churchmen were soonest enabled to do this, for obvious reasons. By the middle of the 13th century so many villeins had become possessed of fiefs, that even St. Louis, who favored the rise of the people, became alarmed, and sought to put a stop to the practice. But he did not take from them the fiefs

they had acquired, which has justly been held to prove that the number of such fiefs was large, and the class of emancipated *coloni* too numerous to be assailed. Louis X., in 1315, emancipated all persons in the royal domains upon their paying a fair composition, his object being to set an example to all seigneurs; but his example was not extensively followed. Philip the Fair had emancipated the villeins on the royal domains in Languedoc, but the number of freemen was always greater in southern France than in the north, except in Normandy. One of the chief effects of the crusades was to favor emancipation. Previously the obstacles in the way to emancipation were almost insurmountable. The labor of the villeins was very valuable to their lords, and a lay noble "was unable to enfranchise the serf without the concurrence of each in turn of the various other lords who, in the long chain of feudal dependence, might have an interest, mediate or immediate, or more or less remote, in the fief to which the serf belonged." To emancipate a serf on an ecclesiastical estate would have been to alienate a part of the church's property, and that property was inalienable according to the canon law. The crusades operated to change this, as military service was incompatible with the servile condition. The serf who took the cross became free, not through the force of positive law, but because opinion was so strong in his favor that his owner durst not reclaim him, either while in service or after his return. The crusades, too, by introducing unwonted habits of change of place, greatly increased the numbers of those vagrants whom the law had previously presumed to be serfs, and assigned to the lord on whose property they remained beyond a year and a day, unless they acknowledged themselves to be the property of some other lord. The crusaders were soldiers of the cross, and it would not answer to deal with them as slaves. It was allowed to vagrants to declare themselves the king's vassals, and such vassals were free. Further, this movement of the people caused great additions to be made to the populations of the communes, and the gates of the communes stood constantly open to refugees; and whoever resided therein for a year and a day, being a serf at the beginning of that term, became a free man. No serf could be a *bourgeois*, for in the citizens of a bourg resided, collectively, its seignury; and a serf could not hold seignorial rights. But when the serf who had taken refuge in a bourg had acquired freedom, he became a citizen on easy terms. Before the crusades these bourgs had become so many places of refuge to men of servile condition; and the crusades led to the great increase of the number of such fugitives, promoted commerce, and created new sources of wealth, which things were favorable to freedom. Nevertheless, serfdom was not abolished throughout France until the French revolution, and serfs could not be manumitted without letters patent from the king. It was

a French rule of law, and as such put in practice concerning foreigners as early as the 13th century, that whoever entered France, being a slave, became free; but the practice of the country was very different toward the masses of the natives. That terrible insurrection known as the *Jacquerie*, which occurred in 1358, shortly after the battle of Poitiers, was caused by the sufferings of the people at the hands of the seigneurs, though its immediate occasion was the additional suffering created by the English wars. The fierceness of the peasants afforded an excuse for keeping them in a subordinate condition; and from that time the progress of emancipation became slow. The triumph of the central power, too, was injurious to the servile classes, as the kings no longer had occasion to favor the people at the expense of the nobles. From the closing years of the 14th century, therefore, the condition of the French people ceased to be directly affected by those causes which previously had tended to their elevation; but general causes to that end still remained in operation, and at least prevented their condition from becoming worse.—In Italy the people had become free by the 13th century; and in some of the German countries the peasants acquired their freedom before the close of the 18th, but in other parts of the country they remained in a condition of modified villenage until the present century.—In England the state of most of the laboring people was on the whole, and comparatively speaking, mild down to the time of Henry II. (1154-'89). The *villani* of Domesday Book were the *ceorls* of Anglo-Saxon law; and in the second generation after the Norman conquest the villen was mentioned as a freeman. But in the next generation he became completely dependent upon the lord, and his general condition was very harsh, though somewhat mitigated by the existence of legal fictions, and by opinion. "This class," says Hallam, "was distinguished into villeins regardant, who had been attached from time immemorial to a certain manor, and villeins in gross, where such territorial prescription had never existed, or had been broken. In the condition of these, whatever has been said by some writers, I can find no manner of difference; the distinction was merely technical, and affected only the mode of pleading." Gradually the condition of the English villeins was improved, until the system silently disappeared. By the middle of the 14th century there were many peasants who had become free laborers, and who worked for wages. The English villeins of that time shared in that general aversion to servitude which led the *Jacques* to rise in France, and the rebellion that takes its name from Wat Tyler was of substantially the same nature as that in which Guillaume Callet figured, though the English revolt was a quarter of a century later than the French. From the close of the 14th century the tendency to the abolition of English

villanage was very strong. The last unequivocal evidence as to its existence is believed to be a commission of Elizabeth, dated 1574, directing the enfranchisement of her bondmen and bondwomen on certain manors, upon payment of a fine; but no doubt it existed somewhat later than that period.—The Polish peasantry were enslaved by the nobles, though they were never chattel slaves; and among the causes of the fall of Poland was the serfdom that there existed. After its last partition the condition of the Polish peasants underwent various modifications under the Prussian, Austrian, and Russian governments, until emancipation, though at different periods, was decreed in each division. In Hungary, the last remnants of serfdom were abolished by the laws of 1848. In Russia, serfdom was unknown till the end of the 16th century, though chattel slavery had long existed there. Serfdom was introduced by Boris Godunoff, and in a few years all the rural populations were subject to it, with the exception of those persons who resided in the free communes constituting the crown domains. The legislation of Peter the Great transformed the serfs on private estates into a condition of chattelhood, while those on the royal domains enjoyed comparative freedom; but as great grants of land and serfs were made by the Russian sovereigns to individuals, myriads of peasants were thus converted into serfs of the lowest grade. Alexander I. and Nicholas were friendly to the liberation of the peasants; and Alexander II. soon after his accession began his labors in the cause of emancipation, proposing to free all the serfs, but gradually. He encountered considerable opposition, and long preparations were unavoidable; but on March 3 (Feb. 19, O. S.), 1861, the "imperial manifesto" emancipating the serfs was published, to take effect at the end of two years. Serious difficulties were anticipated from the opposition of the nobles and the ignorance of the serfs; but the manifesto was carried out with little disturbance. (See RUSSIA.)

SERGEANT, John, an American jurist, born in Philadelphia, Dec. 5, 1779, died there, Nov. 23, 1852. He graduated at Princeton in 1795, became distinguished as a lawyer, and between 1815 and 1842 served six terms in congress. In 1826 he was one of the two envoys appointed to represent the United States in the Panama congress. In 1832 he was the whig candidate for vice president with Mr. Clay. A volume of his "Select Speeches" was published at Philadelphia in 1832.

SERGIPE, a maritime province of Brazil, the smallest in the empire, bounded N. by Alagoas, from which it is separated by the Rio São Francisco, E. by the Atlantic, and S. and W. by Bahia; area, 12,240 sq. m.; pop. in 1871, 275,000. It has a coast line of 130 m., with few indentations and no good harbors. The shore in the southern half is mostly low and sandy; in the northern there are scattered hills. The

E. part of the province is called the *mattas*, from its forests, which produce valuable timber, and are here and there separated by cultivable land; the western, called the *agrestes*, is mostly a barren waste, with some portions fit for pasturage in the rainy season. The latter region is the higher, and somewhat mountainous, the principal range being the low Serra d'Itabayana. Besides the São Francisco, there are several small rivers falling into the Atlantic, none of them navigable by small craft for more than 27 m. from the sea. In the shore region the climate is hot and the soil fertile, yielding large crops of cotton, sugar cane, tobacco, mandioca, rice, and millet; some flax is produced, and mangoes and oranges abound. The exports include cotton, sugar, tobacco, rum, and ipecacuanha. The number of schools reported in 1875 was 149, with a total attendance of 5,247. Capital, Aracajú, near the mouth of the Cotinguiba river.

SERINAGUR, a city of India, capital of Cashmere, by which name it has also sometimes been called, in lat. 34° 6' N., lon. 74° 55' E., near the centre of the valley of Cashmere, 5,246 ft. above the sea, 170 m. N. N. E. of Lahore; pop. about 135,000. It extends about 4 m. along both sides of the Jhylum, which is crossed by five wooden bridges, and winds through the town as a deep and placid stream about 100 yards wide. The exterior appearance of Serinagur is picturesque and attractive. From its delightful situation and innumerable canals it has been called the Venice of Asia; but within it is for the most part extremely filthy. The houses, which are generally dilapidated, are built of thin bricks with timber frames, many of them three stories high. The principal public buildings are the Jumna Masjid, or great mosque, in which it is said 60,000 persons can worship together, and the dungeon-like palace of the maharajah, surmounted by a shining cupola. On the east is a lake 5 m. long and 2½ m. broad, known as the Dal of Serinagur, which is connected with the Jhylum by a canal, is surrounded by beautiful scenery, and was formerly a favorite resort of the Mogul emperors, many of whose pleasure grounds and palaces still remain; the most noted is the Shalimar Bagh, laid out by the emperor Jehanghir, which Moore selected for the closing scene of "Lalla Rookh." This lake is celebrated for its floating gardens, formed by placing layers of soil on tangled masses of aquatic plants, where the finest melons and cucumbers are cultivated. Serinagur is the centre of the shawl manufacture of Cashmere. Silk is also raised and manufactured.

SERINGAPATAM (Hindoo, *Sringa-patna*), a city of India, in Mysore, 7 m. N. E. of the city of Mysore, 2,412 ft. above the sea; pop. about 13,000. It is on the upper end of an island, about 3 m. long, in the Cavery river, and was strongly fortified under native rule. The more prominent buildings are a Hindoo temple, a handsome mosque, the mausoleum of Hyder

Ali and Tippoo Sahib, and the ancient palace of the rajahs of Mysore. Seringapatam first appears historically in 1610 as the capital of a Mysore chief named Raj Wadegar, and was unsuccessfully besieged by the Mahrattas in 1697. In 1765 Hyder Ali established his government there, and a Mahratta army again attacked the city in 1772 and forced him to a humiliating peace. During the reign of Tippoo Sahib, in 1792, it was invested by a large British force under Lord Cornwallis, who exacted a war indemnity of £3,300,000 from the native monarch, together with the cession of about half his dominions to the English and their allies. In 1799 Seringapatam underwent a celebrated siege. It was invested by the British and the allied forces of the nizam, about 31,000 strong, under Gen. Harris, on April 6, and was stormed and captured on May 4, after four days' bombardment, and a loss to the British of 1,164 killed and wounded. The assault was led by Gen. Baird, and Col. Wellesley, afterward duke of Wellington, participated in it. Tippoo Sahib was killed, and 929 pieces of ordnance, together with enormous amounts of treasure and jewels, fell into the hands of the victors; £1,100,000 in prize money was divided among the troops. In 1809 the discontent with the management of the Madras army led to a mutiny of the European officers stationed at Seringapatam, who fired upon the royal troops, but subsequently submitted. Seringapatam is now included within the Ashtagram commissionership of Mysore.

SERPA-PINTO, A. A. See supplement.

SERPENT, a musical wind instrument of curvilinear form, consisting of a conical tube of brass, divided into three parts, a mouthpiece, neck, and tail, and having six circular apertures for the production of the notes. Its compass extends from B flat below the bass staff to G, the treble clef line, and its use is confined to military bands. It was invented by Edme Guillaume of Auxerre in 1590.

SERPENT, or **Snake**, the common name of the ophidian reptiles, including, according to the earlier naturalists, all air-breathing oviparous vertebrates, of elongated and rounded body, without limbs and creeping on the ventral surface. The body is very flexible and narrow, without distinct neck and with conical tail; bones of the face movable, making the mouth very dilatable; teeth sharp, separate, usually hooked on both jaws and almost always on the palate; no eyelids, nor tympanum, nor apparent external auditory foramen; skin extensible, protected by thin scales covered by an epidermis which is shed in a single piece by a process of inversion; the plates of the under surface are larger, and used for progression; the male reproductive organs are double, concealed, and capable of protrusion, which has led some to the belief that snakes have posterior limbs; they are oviparous, and a few are ovoviviparous, and the young undergo no metamorphosis after leaving the egg. The

spine consists of very numerous and movable vertebrae, concave in front and hemispherically convex behind, distinguishable only into costal and caudal; the occipital condyle is single, and the jaws are connected by a very movable interarticular bone; the very numerous ribs are always distinct and free at the lower end, there being no sternum nor pectoral arch. The tongue is soft and fleshy, protractile, deeply forked, and held in a sheath; the visceral organs are very long, closely fitting in the abdominal cavity; only a single lung well developed, generally the left, forming a cavity with spongy walls, and the hinder portion frequently without cells, its simple sac serving probably as a reservoir of air; opening of the cloaca transverse. The vertebrae are rarely fewer than 100, and in some boas and pythons as many as 400, presenting the largest number among animals; progression is almost always by lateral undulations, the ribs with their attached ventral plates being so many pairs of feet, like those of myriapods, in some boas more than 300 pairs; the anterior limbs are wanting, but in some boas and pythons there are horny hooks appearing externally, supported on a rudimentary pelvic arch; with these few exceptions posterior limbs are wanting. Most of the muscles are specially adapted for acting on the spinal column, and are arranged in a very complicated manner, especially those in connection with the ribs. The brain is small, and the spinal cord very long, with exceedingly numerous vertebral nerves. For other details of structure see **COMPARATIVE ANATOMY**, and **REPTILES**. They creep, spring, climb, swim, constrict, suspend themselves by the tail, burrow, and raise the body almost erect. Like most reptiles, they are very sensitive to cold, becoming lethargic in winter; the muscular irritability is remarkably great and persistent, depending on the spinal nervous agency and the inherent property of the muscular tissue; the heart palpitates long after it has been removed from the body, and the jaws open and shut in the decapitated head. The senses of smell, hearing, and taste are very imperfect; the eyes, without lids and constantly open, appear immovable; the principal seat of touch is in the soft and extensible tongue. The scales offer every variety of color and marking, but in most the general color resembles the objects on which they habitually live; the coloring matter is in the middle layer of the skin, the inner or dermis being strong and holding the scales, and the outer or epidermis shed several times a year; the animal is dull and does not eat at the period of casting its skin. These characters are sufficient to distinguish serpents from large annelids, eel-like fishes, the scincoid and chalcidian saurians, and many elongated batrachians; they are reptiles in the true sense of the word. For the systems of classification see **HERPETOLOGY**; they are generally divided into the two groups of the venomous and non-ven-

omous; the first, like the cobra, rattlesnake, and viper, have movable fangs in the upper jaw communicating with a poison gland. All feed on living prey, which is swallowed whole; while some are rapid in pursuit, others crush their victims to death, or poison them, or bring them within reach of their jaws by a kind of fascination, terrifying by their hideous and menacing aspect some of the active and smaller mammals and birds into a momentary loss of power. They eat and drink rarely, and are capable of sustaining very long fasts; digestion is performed very slowly; the secretion of the large salivary glands is profuse. For details on the poison apparatus see COBRA DE CAPELO, RATTLESNAKE, and VIPER. The stomach is little more than a prolongation of the œsophagus, and the intestines are very short; the heart is in a fibrous pericardium, and consists of two auricles, and one ventricle with two unequal apartments communicating with each other; hence a mixed arterial and venous blood is sent over the system; the growth is slow, and the life prolonged; the hissing attributed to serpents is a faint sound produced by the slow escape of air through the mouth or nostrils during expiration, and only exceptionally would be noticeable by an indifferent observer; the animal heat is low. The males are smaller, more slender, brighter, and more active than the females; no nest is made, there is no incubation (except in the python) by the heat of the body, no food is stored up for the young, and no education nor parental care is necessary. The mother hides the eggs in a suitable place, and leaves them to be hatched by the heat of the sun and air; sometimes the young are brought to maturity in the mother's body, as in the vipers. There are about 1,000 described species, widely distributed over the world, especially in the warmer regions; doubtless many varieties from age, sex, and climate have been described as species.—Fossil remains of serpents have been found in all the divisions of the tertiary age; *palæophis* (Owen), attaining a length of 20 ft., has been found in the eocene of England, showing a higher temperature than now exists in N. Europe; many more species, probably belonging near the genus *coluber* (Linn.) if not in it, are met with in the middle and upper tertiary and the diluvium of Europe. Prof. Marsh describes in the "American Journal of Science" (1870) the *dinophis grandis* from the New Jersey tertiary greensand, a vertebra of which indicated an animal 30 ft. long, allied to the present marine boas. Almost all the species older than the post-pliocene are related to the constrictors. He draws attention to the fact of the occurrence of closely related large serpents in the same geological formations in Europe and in this country, just after the disappearance of the snake-like mosasaurus and its allies, interesting in view of the probable derivation of the serpents. Other large species have since been described in

the same journal.—For interesting information on serpents, see Broderip's "Note Book of a Naturalist," part 13, and F. Buckland's "Curiosities of Natural History" (London, 1859).

SERPENTINE. See MARBLE, vol. xi., p. 147.

SERRANO, Francisco, duke de la Torre, a Spanish statesman, born at San Fernando, near Cadiz, in 1810. He entered the army when still a boy, and took part in the war against the Carlists. In 1843, during the contest between the partisans of Maria Christina and Espartero, he espoused the interests of the former, and was one of the junta of Barcelona which declared the majority of Queen Isabella and deposed Espartero. After the restoration of Maria Christina he joined Narvaez in overthrowing the ministry of Olózaga. In 1846 his extraordinary influence over the queen, whose lover he was, led to dissensions between her and her husband, and caused much scandal; and the ministry of Sotomayor attempted to remove him from court, but was overthrown by him. The Pacheco-Salamanca ministry, which he supported, fell before public opposition; and Serrano then, as an offset to the rising favor of Narvaez, caused the recall of Olózaga and Espartero. On the advent of Narvaez to power in 1849, Serrano was made captain general of Granada; and he afterward vigorously opposed in the senate the ministries which rapidly succeeded each other. In February, 1854, he was implicated in an insurrectionary movement at Saragossa, and exiled, but was restored by the revolution of July, and joined the "liberal union" which supported the coalition of Espartero and O'Donnell; and when they separated, Serrano declared for the latter. He had been made in 1854 captain general of artillery, which office he exchanged some time later for that of captain general of New Castile. Madrid being thus under his control at the time of O'Donnell's *coup d'état* in July, 1856, he suppressed the insurrection in the Prado and the Retiro, and soon afterward superseded Olózaga as ambassador to Paris, but was recalled on the fall of O'Donnell in October. On his return he joined in the senate the opposition which led to the downfall of Narvaez in November, 1857. In 1860 he was appointed captain general of Cuba, and was succeeded by Dulce, Dec. 11, 1862. On his return to Spain he was created duke de la Torre for his services in the reannexation of Santo Domingo to Spain in 1861. In June, 1865, he was made captain general of Madrid. On the return of Narvaez to power in 1866, Serrano as president of the senate, with Rios Rosas, president of the deputies, presented a protest against the prorogation of the cortes, and in consequence was imprisoned for a short time at Alicante. In the revolution of 1868 he took a prominent part. With other generals he had been exiled to the Canary islands in July, but the revolutionists sent a vessel for them, and they landed on Sept. 19 at Cadiz. At the head of the insurgents Serrano

defeated the government troops at Alcolea, Sept. 23, and entered Madrid on Oct. 3. The junta made him president of the council and commander-in-chief of the army; and in February, 1869, with the consent of the cortes, he assumed the executive power. The new constitution was promulgated in June, and on the 15th, by a vote of the cortes, Serrano became regent. He resigned that office on the arrival of Amadeus to take the throne, Jan. 2, 1871, and was made prime minister. In April, 1872, he was appointed to the chief command of the forces sent against the Carlists, with whom he concluded in May the convention of Amorovieta; and on his return he succeeded Sagasta as head of the ministry. His concessions to the Carlists in the late convention were the cause of much popular dissatisfaction, but the cortes passed a vote of approval. The insurrection however was still active; the republicans also threatened armed opposition; and in the difficulties which beset Amadeus, Serrano suggested that the ministry should have the power to suspend the constitutional guarantees when they should deem it necessary. Amadeus refused; Serrano and his cabinet resigned, and he was succeeded by Zorrilla. After the proclamation of the republic following the abdication of Amadeus (Feb. 11, 1873), Serrano was conspicuous in the opposition to the new government, in April became implicated in a seditious movement, and fled from the country. With the restoration of quiet he soon returned, and in February, 1874, after the *coup d'état* by Pavia, which followed the resignation of Castelar's administration, he was elected by the cortes president of the republic. He almost immediately placed himself at the head of the army against the Carlists, whom he engaged with varying success till May, when he returned to Madrid. In August he obtained a recognition of his government and the republic by Great Britain, France, and Germany, in September resumed command of the army against the Carlists, and in January, 1875, retired from office on the proclamation of Alfonso XII. as king of Spain.

SERTORIUS, *Quintus*, a Roman general, born at Nursia, in the country of the Sabines, about 121 B. C., assassinated in 72. He distinguished himself in the campaign of Marius against the Cimbri and Teutons, was tribune in Spain under the prætor Didius, joined the party of Cinna and Marius upon his return, and when Marius was driven from Italy raised fresh troops with Cinna and upheld the fortunes of the party. In the subsequent triumph of Marius, Sertorius was the only one of his adherents who exhibited any moderation of conduct; and so strongly was he incensed by the excesses committed at this time, that after the death of their chief he put to the sword 4,000 slaves who had been the body guard of Marius, and had perpetrated every possible crime against the citizens. When Sulla returned to Italy in 83, Sertorius obtained the post of proconsul of

Spain, where he governed with justice. An army having been sent against him by Sulla, he was forced after a temporary success to cross into Africa, where, joining the native princes, he defeated Sulla's general Paccianus. Returning to Spain, he placed himself at the head of the Lusitanians, and defeated the four Roman generals who held possession of the greater part of the country. His design was to found an independent power in Spain, in which the native Spaniards should enjoy equal rights with the Roman settlers. He gained the affection of the inhabitants, and impressed them with a superstitious awe by means of a white fawn which he pretended had been given to him by Diana. The Roman senate at length sent Pompey with a large force against Sertorius, and the first battle took place near Sucro. The force under the command of Perperna was beaten by the Romans under Metellus; but the Romans under Pompey were beaten by Sertorius, and Pompey himself was wounded. Pompey was a second time beaten on the plains of Saguntum, and compelled to withdraw beyond the Pyrenees. Reënforced from Rome, he began a second campaign, but through the summer of 73 failed to bring Sertorius to battle or to gain any material advantage. An offer was finally made of 100 talents and 20,000 acres of land to any Roman citizen who should kill Sertorius; and he was slain by conspirators at a banquet to which he had been invited by his own general Perperna.

SERVAL (*felis serval*, Linn.), a carnivorous animal of the cat family, a native of southern Africa. It is about 4 ft. long, of which the tail is 15 in.; the color above is ochrey yellow, darkest on the back, and shading into white on the under parts; body with dark brown spots forming longitudinal marks on the neck and shoulders; inside of fore legs with two transverse black bands; tail tipped and

Serval.

ringed with black. The legs are rather long, the body slender, the head small and rounded, and the hair long and shaggy, especially on the flanks. It is about the size of the lynx, and preys upon the smaller mammals and birds; it is not very savage, and the young are gentle like the common cat.

SERVANT. See MASTER AND SERVANT.

SERVETUS, *Michael*, a Spanish author, born at Villanueva, near Saragossa, in 1509, burned at

the stake in Geneva, Oct. 27, 1553. His proper Spanish name was Miguel Serveto. He studied law at Toulouse, but having become a disbeliever in the Trinity, he removed in 1530 for safety to Basel. In his 22d year he published *De Trinitatis Erroribus* (Hagenau, 1531), for which he was banished from Basel. In 1532 he published at Hagenau *Dialogorum de Trinitate Libri duo: de Justitia Regni Christi Capitula quatuor*, in which he defended his former book, and advanced a new heresy concerning the eucharist. Changing his name on entering France to Michel de Villeneuve, he devoted himself for some years to the study of medicine in Lyons (where he also worked as a corrector of the press), and afterward in Paris. He was at the university of Orleans in 1534. In 1535 he edited the works of Ptolemy with Latin notes. In the next year he graduated M. D. at Paris, and soon became celebrated as a lecturer on medical science. He divined the true method of the circulation of the blood, and with this and other conjectures in physiology anticipated Harvey and Hunter. In 1537 he published *Syruporum Universa Ratio*. He established himself at Charlieu, near Lyons, in 1538, and in 1540 removed to Vienne in Dauphiny, where he lived for several years in the palace of his former pupil the archbishop. He revised a new edition of the Bible, founded upon the manuscripts of Sanctes Pagninus, which was put under the ban of the church; and gathered the materials for *Christianismi Restitutio*, the manuscript of which was completed in 1546, and sent to Calvin for corrections and suggestions. But the Genevan reformer retained it, and freely accused the author of heresy in letters to others of the Reformed clergy. The work was printed at Vienne in 1553, and the author was arrested and imprisoned for trial. On April 7 he escaped in disguise and reached the frontier; but his trial went on, and he was sentenced to pay a heavy fine and be burned by a slow fire. The edition of his book was destroyed, only three copies being saved. Servetus, on his way to Naples, stopped at Geneva for a month, and at the instance of Calvin was arrested. On Aug. 14 he was brought before the municipal court, accused of heresy, of publishing seditious books, of disturbing the churches, of escaping from the lawful authority, and of insulting the ancient fathers and the living divines of the Protestant church, especially Calvin. On the following days new charges were added, of Anabaptism, of pantheism, of contempt of the Bible, and of materialism. Though the result of the trial could not be doubtful, it was agreed that the matter should be submitted to the decision of the Swiss churches. A paper containing 38 articles was drawn up by Calvin, and, with the answers of Servetus annexed, was sent to the various churches. The opinion of all was that Servetus should be condemned as a heretic, while they differed as to the severity of the

punishment. In the final council of 60 summoned in October, the discussion lasted three days, but in the end the extreme party prevailed. The execution took place on a hill a short distance from the city. No exhortations could induce Servetus to retract, and his last words were a repetition of his heresy. His books and the manuscript which he had sent to Calvin were burned with him. Servetus had no disciples while living, but after his death the name of "Servetists" was fixed as a stigma upon the Swiss Anabaptists, and accepted by a small party who rejected the doctrine of the Trinity.—His life has been written by Mosheim (Helmstedt, 1750), Tréchsel (Heidelberg, 1839), and W. H. Drummond (London, 1848). See also Brunnemann, *M. Servetus* (Berlin, 1865).

SERVIA (Slav. *Serbia*; Turk. *Syrrp*), a state of Europe, tributary to Turkey, bounded N. by Slavonia and Hungary proper, E. by Wallachia and Bulgaria, S. by districts of the vilayets of Prisrend and Bosnia known as Old or Turkish Servia, and W. by Bosnia; area, 16,817 sq. m.; pop. in 1873, 1,338,505, all Serbs, of Slavic origin, excepting about 140,000 Wallachs, 25,000 gypsies, and 15,000 Turks, Bulgarians, Jews, Germans, and Hungarians. The surface is broken by ramifications of the Carpathians in the northeast, of the Balkan in the southeast and south, and of the Dinaric Alps in the west. The highest summits in the east and south reach an altitude of upward of 4,000 and 5,500 ft. respectively. Most of the mountains are covered with dense forests. In the centre and along the banks of the principal rivers are extensive plains. The Danube and its tributary the Save flow on the N. frontier (the former for some distance also on the eastern), and receive the drainage of the country by several streams, the most important of which are the Drina, Morava, and Timok. The principal towns are Belgrade, the capital, Kraguyevatz, Semendria, Uzhitza, and Shabatatz. The climate is severe in the uplands, but mild in the valleys; in winter the thermometer generally ranges between 6° and 14° F. The low grounds are very fertile, and cereals are raised in abundance; good white wine is produced near Semendria; tobacco, hemp, fruit, and some cotton are raised; but horses, cattle, sheep, and swine are the principal sources of wealth. The exports, including grain, skins, wool, cattle, and especially hogs, amounted in 1872 to \$6,000,000, and the imports, chiefly salt, sugar, and manufactured goods, to about the same. Valuable minerals abound, but are not fully worked. Manufactures consist mainly of articles for home consumption. The powder, firearms, and accoutrements required for the army are made in the government works at and near Kraguyevatz. Complete freedom of commerce is guaranteed in the Ottoman empire.—The Serbs are among the most spirited of the Slavic races. There is no nobility, and the peas-

ants are free householders. Community of interests prevails among the laboring classes, who live together under the authority of a chief or "father of the house," of their own selection. The Greek religion is that of almost all the inhabitants, and there is a synod consisting of the metropolitan at Belgrade and three bishops. Secession from the church is rigorously prohibited; but Roman Catholics (about 5,000), Protestants (400), and Jews (1,500) enjoy religious liberty. Education in the higher branches is better provided for by the government than in the lower by the communes, and in the elementary schools is free and obligatory. The academy of Belgrade was made a university in 1869.—Servia pays to Turkey an annual tribute of 2,300,000 piasters, and has enjoyed since 1834 a perfect autonomy, which was confirmed by the treaty of Paris of March 30, 1856, and guaranteed by the European powers. The right of garrisoning Belgrade and other fortresses was finally relinquished by the Porte in 1867. In 1872 a postal treaty was made with Roumania. Commercial treaties were concluded with Russia and Austria in 1874, and Servia established her own coinage in 1875. There are Servian diplomatic agents at Constantinople and Bucharest, and many foreign consular and diplomatic agents reside in Belgrade, the national capital. The government is a limited monarchy, vested in a hereditary prince of the Obrenovitch dynasty, who appoints responsible ministers. The original charter dates from 1838. The latest revised constitution, that of 1869, converts the senate, consisting of 17 life members appointed by the government, into a permanent council of state, and vests legislative power solely in the *skupshchina* or assembly (the origin of which is traced back to the earliest period of Servian history), and provides for its annual meetings at Kraguyevatz. In 1874 the *skupshchina* consisted of 184 members, 101 elected by the people for three years, and 33 appointed by the government. A so-called great *skupshchina*, with about 500 members, assembles in the event of a vacancy on the throne, or in other extraordinary emergencies. Suffrage is universal for all Christian Servians 21 years old and over, who pay direct taxes; only menials and gypsies are disfranchised. All electors are eligible to the *skupshchina* excepting members of the government and of the clergy. The prefects of the 17 circles and the 54 districts are appointed by the government, and the presidents of the communes, who are at the same time justices of the peace, are elected by the people. There are superior courts of law in each circle, besides a court of appeal at Belgrade. The courts are all public, and the independence of the judges is guaranteed by the constitution. The military forces comprise a standing army and a national army (militia). The second forms the nucleus of the military organization; the standing army is only employed on ordinary garrison duty and in train-

ing the national army for war. All able-bodied men must serve between the ages of 20 and 50; the period of service in the standing army is three years, and in the national army 27. The officers of the national army are trained at a central military college, and the non-commissioned officers and men in district schools and shooting grounds. The strength of the standing army is about 12,000 men (divided into garrison troops and reserve), and of the national army (first and second levies) 150,000.—The original inhabitants of Servia were chiefly Thracians. Conquered by the Romans during the early period of the empire, Servia formed part of Illyricum under the name of *Moesia Superior*. During the great migration of nations it was overrun by the Huns, Ostrogoths, and other barbarians, and subsequently was under Byzantine rule from the middle of the 6th till early in the 7th century, when it was devastated by the Avars. The latter were driven out by the Serbs, a Slavic people, who had been living N. of the Carpathians, and whose aid the emperor Heraclius (died 641) had invoked. He allotted to them the depopulated regions, and introduced Christianity. Servia remained a vassal state of the emperors of the East; but a spirit of liberty was fostered by powerful and well organized local governments, whose chiefs (*zhupans*) repeatedly attempted to make themselves altogether independent. But the imperial authority was fully restored in the latter part of the 9th century by Basil I., surnamed the Macedonian. Subsequently the Bulgarians held the ascendancy in Servia for a long period, but their power was broken by John Zimisce, and finally destroyed by Basil II. in 1018. Stephen Bogislas was the first Serb to found an independent principality, about 1043; his son Michael (1050-'80) styled himself king (*kral*), and was recognized by the Roman see. Stephen's grandson Bodin (1080-'90) extended his dominions, but was captured by the Byzantines, with whom his successor Vulkan or Vuk made peace in 1094. Urosh I. joined (1127-'9) the Hungarians against the Greek emperors, laying the foundation of repeated alliances with Hungary; and the contests with Constantinople continued under his successors. Stephen Nemanja, grandson of Urosh II., founded a new dynasty in 1165. He conquered Bosnia and other territories, and made Rassa (now Novibazar) his capital, from which his realm was called the Rascian, but could not cope with the emperors of Constantinople. His son Stephen I. was crowned in 1217 as king of Servia, and his successors acquired much additional territory. The most illustrious of them was Stephen Dushan (1336-'56), who had himself crowned czar. He conquered nearly all Macedonia, Albania, Thessaly, northern Greece, and Bulgaria, and greatly improved the laws, learning, and trade. But conflicts among the governors of his provinces undid his work, and most of his conquests

were lost by his son, King Urosh V., whose assassination in 1367 closed this dynasty. He was succeeded by the waywode (governor) Vukashin, who fought with the Greeks against the Turks, and conquered Salonica in 1369, but was defeated and fell in battle in 1371. Lazarus I. in 1374 established a new dynasty by conquering most of the Servian dominions. In 1389 he was defeated by Amurath I. on the high plains of Kosovo, and executed by order of the sultan, who had received a mortal wound from the hands of a brother-in-law of Lazarus. His son and successor Stephen, first as a vassal and then, in conjunction with the Hungarians, an adversary of Turkey, died in 1427 without issue, and was succeeded by his nephew George Brankovitch. He combated his son-in-law Amurath II., together with John Hunyady, who, after repeated victories, was vanquished in October, 1448, also on the plains of Kosovo. The sultan Mohammed II. completed the conquest of Servia in 1454, but in 1456 was compelled by Hunyady to raise the siege of Belgrade, a year before the death of Prince George of Servia. The latter's son Lazarus II. obtained the succession by poisoning his mother and expelling his two brothers. He died in 1458, the last and the worst of his dynasty. In 1459 Mohammed II. incorporated Servia with Turkey, excepting Belgrade, which was held by the Hungarians until taken by Solymán the Magnificent in 1521. The Turks resented the heroic resistance of Servia by sending 200,000 of her citizens into captivity, and by exterminating whole families, while others emigrated to Hungary; and rapacious pashas ruled abominably for several centuries, and reduced the country almost to a wilderness. Austria received Belgrade and most of northern Servia at the close of her war with Turkey in 1718, but the peace of Belgrade (1739) restored the Turkish domination, and the Serbs were again subjected to dire calamities, especially by the excesses of the janissaries. Their repeated applications for redress remaining unheeded at Constantinople, the people at length rose against the Turks, and Czerny George, a peasant, became in 1805 a successful leader of the revolt, and in 1807 was recognized as chief of the Servians by the sultan. (See CZERNY GEORGE.) After the treaty of Bucharest of 1812, Servia was deserted by Russia and France, and in 1813 the Turks again became masters of the country. But in 1815 Milosh Obrenovitch put a final end to their absolute domination. The stepbrother of Milan Obrenovitch (son of Obren), whose name he assumed, he began life as a grazier, but subsequently became one of the most valiant officers of Czerny George, and in 1813 showed so much firmness that the Turks left him in charge of several districts and at the head of several thousand men, in the hope that he would reconcile the people to their rule. But he awaited only an opportunity for its overthrow, and finally on Palm Sunday, 1815, gave

the signal for an insurrection. He defeated the Turks repeatedly, and secured in 1816 a partial independence for Servia; and after being head of the provisional government, he was elected hospodar or prince in November, 1817, and subsequently recognized by the sultan. He incurred the hostility of former chiefs, and attempted in vain to allay agitation by adopting in 1835 a liberal statute and the *code Napoléon*. Russia and Turkey concocted a new statute, which the sultan promulgated, Dec. 24, 1838, in the form of a *hatti-sherif*, instituting a senate, the members of which could not be displaced without the sultan's consent. This body was chiefly composed of Milosh's enemies, who brought charges of peculation against him, it being known that he had large estates in Wallachia and Austria, besides vast funds deposited in Vienna. He was compelled to abdicate, June 13, 1839, in favor of his son Milan, who died on July 7 and was succeeded by Milosh's younger son Michael. Soon after assuming the government he incurred the hostility of the Turks by banishing their most zealous partisans, Vutshitch and Petronievitch, who in 1842 headed an insurrection against him, which resulted in his ignominious defeat. He was driven from Servia on Sept. 7, his dynasty was deposed, and Alexander Karageorgevitch, a son of Czerny (or Kara) George, was elected prince, Sept. 14. His complacency toward the Turks during the Crimean war secured their assent to the placing of Servia, by the treaty of Paris of 1856, under the collective protection of the European powers; but at the same time he made himself odious in Servia for having invoked Turkish assistance for the punishment of his enemies, and Turkish protection in the citadel of Belgrade against his own countrymen. He was deposed Dec. 23, 1858, and Milosh, though almost an octogenarian, was reinstated. He died Sept. 26, 1860, and Michael again became reigning prince. After the disturbances at Belgrade in 1862, Michael obtained in 1867 the withdrawal of the Turkish garrisons from this and all other fortresses. He was assassinated June 10, 1868. (See ALEXANDER KARAGEORGEVITCH.) Prince Michael married Julia Hunyady, but had no children, and had adopted as his son his nephew Milan (born in Jassy, of a Moldavian mother, Aug. 22, 1854), who was educated in Paris (1864-'8), and was elected prince July 2, 1868, as Milan Obrenovitch IV. The sultan, fearing the alleged preference of Russia for the prince of Montenegro as ruler of Servia, not only at once recognized him, but also acknowledged for the first time the hereditary rank of the dynasty. A regency of three members, of whom the minister Blagnavatz, who had chiefly promoted his election, was the chief, conducted public affairs during his minority (1868-'72). Turkey had in 1834 restored six Servian districts which she had retained since 1813, and in the spring of 1872 she relinquished a

few additional localities, though not all which Serbia claims as her own. The majority of Prince Milan was declared on Aug. 22, 1872. His relations with Turkey were complicated in the summer of 1875 by the outbreak of the insurrection in Herzegovina, which excited in Serbia a strong sympathy. The seat of the legislature, which had always been at Kragujevatz, was in October removed to Belgrade. At the first session held in the latter city (Oct. 4) the prince declared himself, contrary to the wishes of the *skupstina*, opposed to a war with Turkey, and appointed a new cabinet in harmony with his conservative views, thereby impairing his popularity.—See Ranke, *Die serbische Revolution* (Hamburg, 1829; 2d ed., 1844); Milutinovitch, *Geschichte Serbiens von 1389–1815* (Leipsic, 1837); Cunibert, *Essai historique sur les révolutions et l'indépendance de la Serbie depuis 1804 jusqu'à 1850* (2 vols., Leipsic, 1855); Hilferding, *Geschichte der Serben und Bulgaren* (Bautzen, 1856); the Rev. W. Denton, "Serbia and the Servians" (London, 1862); Elodie Lawton Mijatovics (William Tweedie), "History of Modern Serbia" (London, 1874); and Saint-René Taillandier, *La Serbie au XIX^e siècle*, Kara George et Milosch (Paris, 1875).

SERVIAN LANGUAGE AND LITERATURE. The Servian language forms, together with the Russian and Bulgarian, the eastern stem of the Slavic languages. In the wider sense of the word, in which it is frequently called the Illyrian or Illyrico-Servian, it comprises the languages of the Serbs proper, the Croats, and the Sloventzi or Vinds. The first of these dialects is spoken by the Serbs in the principality of Servia and in Hungary (in which country they are called Rascians), by the Bosnians, Herzegovinians, Montenegrins, Slavonians, and Dalmatians; the second in the Austrian province of Croatia; the third in the Austrian provinces of Styria, Carinthia, and Carniola. Those Serbs who belong to the Greek church use the Cyrillic alphabet, while those belonging to the Roman Catholic church (comprising chiefly the Dalmatians, Croats, and Sloventzi) have adopted the Roman alphabet. Among the Dalmatians, in former times, the Glagolitic alphabet was in use. (See GLAGOLITIC.) Altogether, according to an estimate of Schafarik, the Servian language is spoken by about 7,250,000 persons, of whom more than 4,500,000 live under Austrian, more than 2,500,000 under Turkish, and about 100,000 under Russian rule.—There are in the Servian language four declensions of substantives and two of adjectives; the dual number has become extinct; the instrumental and the locative cases are found as in other Slavic idioms. The comparative of the adjective is formed by annexing a syllable, generally *yi*; the superlative by prefixing a syllable to the comparative (*nay*). The verb, which is inflected after three conjugations, lacks a subjunctive, which is supplied by circumlocution, and a

passive, which is expressed by means of a special participle. The tenses are the present, the future, the imperfect (with iterative signification), and the preterite. Of the prepositions, some govern the genitive, others the dative or accusative, and the accusative and locative, others the accusative and instrumental, others the genitive and instrumental. The Servian surpasses all the other Slavic idioms in euphony, and has often been called the Italian of the Slavic family of languages. The language of the eastern Serbs has received many Turcisms, but they have not affected its essential structure. The best grammatical work on these languages is the Servian grammar (in the Servian language) by Vuk Stefanovitch Karajitch, of which Jacob Grimm published a German translation (Berlin, 1824) with an excellent introduction. Other scientific grammatical treatises are those of Danicic, *Srpska grammatika* (3d ed., Belgrade, 1863) and *Srpska sintaksa* (1868). A grammar of the Croat language was published by Berlic (Agram, 1842), and another in Latin by Budmani (Vienna, 1867); one of the Dalmatian by Babukie (German translation by Fröhlich, Vienna, 1839). Of the language of the Sloventzi we have a grammar from Kopitar (Laybach, 1808). A dictionary of the Servian language has been published by Karajitch; an Illyrian-German and German-Illyrian dictionary by Richter and Ballmann (2 vols., Vienna, 1839–'40); a German-Illyrian by Mazuranic and Uzarevic (Agram, 1842); and a Croat by Drob-nitsch (Graz, 1852). An extensive Serbo-Croat dictionary is now (1875) in course of preparation by the South Slavic academy of sciences in Agram.—The Serbs who belong to the Greek church had no literature in their own language until the middle of the 18th century. Their writers used the Old or Church Slavic, which however was generally mixed with the popular dialect. The most ancient remnants of this style reach back to the 11th century, and consist principally of documents, diplomas, acts of government, &c., a collection of which was published at Belgrade in 1840. Among the most ancient writers of Servia are Stephen, the first king of Servia (crowned in 1217), who wrote the history of his father; his brother, Archbishop Sava (died 1237), who wrote monastic rules and other works; Domentian (about 1263), who wrote biographies of saints; and especially Archbishop Daniel (1291–1338), the author of the chief work on the ancient history of Servia, called *Rodoslov* ("Genealogical Register"). Count Pucic has collected and published the records, deeds, and laws of the period in his *Monumenta Serbica* (Vienna, 1858) and *Srbski spomenici* (Belgrade, 1858–'62). Of great importance also are the statutes of King Stephen Dushan (1336–'56). The Gospels were printed in Belgrade in 1552. During the following two centuries the only work of note was a "History of Servia," from the origin of the people until the reign of the

emperor Leopold I. of Germany, by Brankovitch (1645-1711). A partial revival began in 1758, when a Slavic press was founded at Venice. The archimandrite J. Raitch (1726-1801) gained a lasting reputation by his "History of the Slavs" (4 vols., Vienna, 1792-'5). But the first who undertook to write a work in the popular dialect was Dosithej Obradovitch (1739-1811), a monk, who for 25 years had travelled all over Europe, and at his death was senator and instructor of the children of Czerny George. His complete works were published at Belgrade in 1833 in 9 vols. Demetrius Davidovitch from 1814 to 1822 edited at Vienna the first Servian newspaper, and Vuk Stefanovitch Karajitch (1787-1864) fixed the present Servian alphabet, and reduced the language to certain general rules and principles. His collection of the Servian popular songs (4 vols., Vienna, 1814-'33) drew the attention of foreign nations to their beauty. In Germany, a general interest in them was excited by Goethe, Talvi (*Volkslieder der Serben*, 2 vols., Halle, 1825-'6), J. Grimm, and others; and many translations have since been published. In England some of the songs have been made known by Bowring and Robert Bulwer ("Owen Meredith"). Among the best modern Servian writers are Simeon Milutinovitch, author of a national epic, *Serbianka* (Leipsic, 1826), describing the Servian war of 1812, and of a history of Servia during the years 1813-'14 (Leipsic, 1837), and Archbishop Mushitzki of Carlovitz, whose works were published at Pesth in 1838. The chief seats of Servian literature are Pesth, Neusatz, and Belgrade. The last named city now has several newspapers, and a university in which law, philosophy, and the sciences are taught. There is also a Servian society of savants, formed in 1847, and reorganized in 1863 with the title of *Srpsko utcheno drustvo*. Collections of the popular poetry of Montenegro have been published by Tchubar Tchoikovitch. —Among the Roman Catholic Serbs, the Dalmatians had as early as the 12th century an interesting literature. An old chronicle of 1161, written in Slavic by a priest of Dioclea, is still partly extant in the original, and wholly in a Latin translation. Toward the close of the 15th century the city of Ragusa became an Illyrian Athens, and produced many distinguished authors, especially poets. The Ragusan and Dalmatian dialects which appear in their literary productions were very similar to the Servian as purified by Karajitch, and through the study of these ancient poets and the labors of L. Gaj, editor of an "Illyrian National Gazette" at Agram, the literary language of almost all the Serbs is now very much the same, though still written partly with the Cyrillic instead of the Roman alphabet. In the beginning of 1868, 14 political, 5 literary, 2 agricultural, 3 pedagogic, and 2 religious periodicals were published in the Servian language. —A good account of the history of Servian

literature, in English, is given in Talvi's "Historical View of the Languages and Literature of the Slavic Nations" (New York, 1850). See also Schafarik, *Geschichte der südslawischen Literatur* (Vienna, 1863-'4).

SERVICE BERRY. See JUNE BERRY.

SERVICE TREE (formerly spelled *servise*, from Lat. *cerevisia*, beer, a fermented drink having been made from the fruit), a European tree belonging to that section of the genus *pyrus* which includes the mountain ashes. The true service tree, *P. sorbus* (or *sorbus domestica*), is barely hardy in England; it is most abundant in France and Italy, and occurs in northern Africa and western Asia. This and the mountain ash were placed by Linnaeus in the genus *sorbus* (Lat. *sorbere*, to drink down, in allusion to their use for making a beverage), and they are sometimes in England called sorbs; but later botanists, finding that the chief difference between these trees and the apples and

Service Tree (*Pyrus sorbus*).

pears consisted in the former having compound leaves and flowers in broad cymes, included them all in the genus *pyrus*. The service tree is long-lived, some specimens being thought to be 1,000 years old; it grows from 20 to 60 ft. high, with a large pyramidal head; the bark is smooth except on old trees, where it is rough and full of cracks; the leaves have six or more pairs of serrate leaflets, with an odd one; the flowers are cream-colored, and the fruit, which is much larger than in any of the mountain ashes, is when ripe greenish brown, with a reddish tinge; eight or more varieties of fruit have been described, but the principal ones are the apple-shaped and pear-shaped, both about the size of a common gooseberry. Its chief value is in its wood, which is considered to be harder and heavier than that of any other European tree, weighing when dry 72 lbs. 2 oz. to the cubic foot, having a compact grain and reddish tinge, and taking a very fine polish; when not properly seasoned it twists

and splits badly; it is much used for screws to wine presses, cogs to wheels, rollers, pulleys, and rules; and for the coarser kinds of engraving it is one of the best substitutes for box wood. The fruit is sometimes eaten, but only when it is ready to decay; when recent it is very acid and austere; its use to make a fermented drink is mentioned by both Virgil and Pliny; in Brittany a cider or perry is made from it which is said to be good, though having a very unpleasant smell.—The wild service tree of England is *P. torminalis*; and the name is sometimes given to the European and the American mountain ash, *P. aucuparia* and *P. Americana*. (See ASH.)

SERVITES, or **Servants of the Virgin Mary**, an order of monks in the Roman Catholic church, founded in Florence in 1233 by seven patrician Florentines. Their main object was to propagate devotion to the Virgin Mary. They lived at first as hermits, but soon became a monastic community under the Augustinian rule. They were approved in 1255 by Pope Alexander IV., founded establishments in every state of western Europe, and were ranked as a mendicant order by Pope Martin V. In 1593 a branch of the order, under Bernardino di Ricciolini, adopted the original eremitical mode of life. The Servites have produced a large number of distinguished men, among whom may be mentioned St. Philip Benizi (died 1285), one of the apostles of western Europe in the 13th century, and Fra Paolo Sarpi. There were also female Servites, who were never very numerous, and a large body of Tertiarians. (See TERTIARIANS.) The order in 1870 was divided into 27 provinces, the central house being the monastery of the Annunziata in Florence. They were subsequently involved in the decrees suppressing religious orders in Italy and Germany. They were introduced into the United States in 1870 by Bishop Melcher of Green Bay.

SERVIVS TULLIVS, the sixth king of Rome, reigned from about 578 to about 534 B. C. According to the legendary accounts of his life, he was brought up in the palace of Tarquinius Priscus. One day, while he was asleep, flames appeared about his head, and Queen Tanaquil prophesied that he would do great things. He grew up in high favor with the king, and received in marriage one of his daughters. The sons of Ancus Marcius, fearing that he would be made heir to the throne, put the king to death; but Tanaquil declared that Tarquinius was not mortally wounded, and caused Servius Tullius to rule in his name. Servius not long after assumed the sovereign power. He added to the city the Viminal, Esquiline, and Quirinal hills, divided the people into tribes, classes, and centuries, and made a new constitution which was designed to give political independence to the commons. His regard for their interests awakened the jealousy of the nobles, and a horrible tragedy was the consequence. His two daughters were

married to the two sons of Tarquinius, and both wives and husbands being of unlike natures, Lucius Tarquinius secretly killed his wife, and married his sister-in-law Tullia, who had murdered her husband. Lucius then plotted with the nobles against the king, and in the summer, when the commons were gathering their harvests, entered the forum with a band of armed men, and seated himself on the throne before the doors of the senate house. Some of his followers slew the king on the way toward the Esquiline hill, and left his body in the road, where the chariot of his daughter Tullia was driven over it. Many of the incidents of this reign are unquestionably fabulous. The constitution, which is historical, was swept away entirely during the succeeding reign. What are called the walls of Servius Tullius were the walls of Rome down to the time of the emperor Aurelian.

SESOSTRIS. See EGYPT, vol. vi., p. 462.

SESTERCE (Lat. *sestertius*), an ancient Roman brass or silver coin, worth a quarter of a denarius, or originally $2\frac{1}{2}$ asses, whence its name (*semis tertius*, the third a half, the Roman expression for two and a half); but the denarius being early divided into 16 instead of 10 asses, the sesterce became equal to 4 asses. Its value down to the time of Augustus was 4.1 cents, and afterward 3.6. The *sestertium* was 1,000 sesterces, and large sums were often counted in sestertia. There was a common formula for the expression of that value in thousands, as: *SS*, 1,000 sestertia; *bi*na *SS*, 2,000; *de*na *SS*, 10,000; and *centena SS*, 100,000.

SESTOS, or **Sestus**, in antiquity, the principal city of the Thracian Chersonesus (now peninsula of Gallipoli), on the Hellespont, opposite Abydos, from which it is distant about 1 m. Though never large, it was important from its position. Its chief celebrity is from its connection with the romantic story of Hero and Leander, the former of whom was a priestess in the temple of Venus at Sestos. The western end of the bridge by which Xerxes crossed the Hellespont was a little S. of Sestos; and from its port the army of Alexander sailed over into Asia. Its site is now called Yalova.

SET, or **Typhon**. See DEMONOLOGY, vol. v., p. 794.

SETI I. and II. See EGYPT, vol. vi., pp. 461-2.

SETON, **Elizabeth Ann**, founder of the sisters of charity in the United States, born in New York, Aug. 28, 1774, died at Emmetsburg, Md., Jan. 4, 1821. She was the daughter of Dr. Richard Bayley, and in her 20th year became the wife of William Seton, whom she accompanied to Italy in 1803. After his death in Pisa she returned to New York, and entered the Roman Catholic church March 14, 1805. The ruin of her husband's fortune having left her dependent on her own exertions, she opened a school in Baltimore; but having received \$8,000 from the Rev. Samuel Cooper, and being joined by her two sisters-in-law, Harriet and Cecilia Seton, with two other la-

dies, they assumed the religious habit, Jan. 1, 1809, at Emmetsburg, and opened there a conventual establishment on July 30. In 1812 the sisterhood numbered 20 members, and chose Mother Seton as superior general, which post she occupied till her death. In 1814 they took charge of an orphan asylum in Philadelphia, and in 1817 were incorporated by the legislature of Maryland. In the latter year they took charge of an orphan asylum in New York, and thenceforward their increase kept pace with the spread of the Roman Catholic church in the United States. The community numbered 50 members at the death of the foundress. (See CHARITY, SISTERS OF.)—See White's "Life of Eliza A. Seton," for the most part an autobiography (New York, 1853; 5th ed., Baltimore, 1865); and the Right Rev. Robert Seton's "Memoir, Letters, and Journal of Elizabeth Ann Seton" (2 vols., New York, 1869).

SETTER (*canis index*, Caius), a sporting dog of the hound group. The head is remarkably developed, the brain very large, and the ani-

Setter.

mal evinces intelligence, affection, and docility. The figure is intermediate between that of the pointer and spaniel, and it is generally considered as descended from the crossing of these two varieties; it resembles a large breed of the spaniel, and is probably of Spanish origin; the hair is long and silky, less smooth than in the pointer, with much of the waved character seen in the spaniel, even on the ears. The best breeds are those of England and Ireland; the most ancient colors were deep chestnut and white; the English setter is generally white with large spots or blotches of liver color or reddish brown; many are marked with black. The natural instinct to crouch at the sight or scent of game has been cultivated in the setter, but they have been taught also to point with the fore foot raised, so that practically the setter and pointer are used in the same way; they are used only as gun dogs and for birds; their sense of smell is very acute. They take to the water better than the pointer, and are better in close coverts; they will work

well with pointers; in the United States they are taught to bring game; they will almost always point at the scent of turkeys, but not of other domestic fowls.

SETTLEMENT. I. Under the poor laws, the right which one acquires to be considered a resident of a particular place, and to claim relief from such city, town, or village, if he stands in need of it. The conditions determining settlement are almost entirely prescribed by statutes, which provide generally in respect to adults that their residence in any place for a defined term of years gives them a settlement therein. A married woman has the same settlement as her husband, though if he has none within the state it may be provided that her own at the time of the marriage, within the state, is not lost or suspended. Legitimate children have the settlement of the father, or of the mother if the father has none in the state. Illegitimate children take the settlement of the mother. In different states serving under articles of apprenticeship or for wages, and the payment of taxes, are made to give a right to a settlement. **II.** In the limitation or disposition of property, a deed or instrument commonly made previous to or in contemplation of marriage, the object of which is generally to limit property in such modes and to such uses as will assure a provision for the wife and the issue of the marriage. Settlements may be made by the wife, but then they are very often made in consideration of a settlement by the husband; or they may be made mutually by husband and wife upon a separation, during the coverture. The common law troubles itself but little with the equitable right of a woman to retain after her marriage some enjoyment of her own property, but chancery has to a considerable extent interposed in her favor. Whenever the husband was compelled to seek its assistance in order to reach the wife's property, chancery obliged him to make equitable settlements out of it in the wife's behalf. It invented also and supported, for the wife's benefit, the contrivance of a separate use and estate; and it favored those contracts, named settlements, which, employing the equity devices of uses, trusts, and powers, were framed for the purpose of securing by express stipulation this same benefit of a separate estate for the wife. The legislature came in time to reform the law in the same direction, and has enacted, both in England and the United States, those "married woman's statutes" which have materially modified the common law touching the rights of husbands over the estates of their wives.—In general, every person who may alienate his property may make a settlement of it. All persons therefore of full age, and masters of their estates, may settle them as they please. Yet a woman, even if she is of full age, cannot in contemplation of marriage, without the knowledge of her intended husband, make a settlement of her property real or personal; the disappointment of the future

husband's expectations respecting the property of the wife is a fraud on the part of the latter, and invalidates the settlement. Nor, at common law, can a woman under coverture make a settlement without the concurrence of her husband, unless she is acting under a power or is disposing of property which she holds in her separate right. Great inconvenience and disadvantage having arisen from the state of the law in regard to the right of infants to make settlements, a statute was passed in England in 1858 which enabled male infants at the age of 20 and female infants at the age of 17, with the approbation of the court of chancery, to make valid settlements, or contracts for the settlement of all their property, real or personal, whether in possession or in reversion, remainder, or expectancy.—Settlements or agreements for settlements may be made before marriage or after it. Equity will enforce ante-nuptial agreements, provided they are fair and valid, and do not contravene the general policy and principles of the law. A subsequent marriage is consideration enough to support an otherwise voluntary deed. Post-nuptial settlements may be made either voluntarily or in pursuance of articles entered into prior to the marriage. In the latter case, the marriage being of itself a valuable consideration, the settlement is valid both against creditors and purchasers. A voluntary settlement made after marriage, and not resting on any ante-nuptial agreement, is in general void as against creditors existing when the settlement was made; yet it may be good, if made for a consideration which bears a reasonable proportion to the amount tied up by the settlement. The concurrence of a wife in destroying an existing settlement, and her joining in barring her dower, have been held sufficient considerations to support settlements which would otherwise have been held voluntary and invalid.—In framing marriage settlements, it is expedient to vest the property in a trustee, though this is by no means indispensable. The control of the separate estate may be committed to the wife. Regard must be had to the provisions of the statutes which fix the limits to the suspension of the power of alienation, and to the statutes respecting trusts and powers which are enacted as checks upon the disposition to tie up property in certain hands.—The necessity of making settlements is materially lessened by the very general enactment of the so-called married woman's statutes to which we have already referred. It is the chief object of the statutes to give the wife rights, independent of the husband, to take by inheritance, or by gift, grant, or bequest, any real or personal property; to hold it to her sole and separate use; to dispose of it as she pleases during her lifetime, and to demise it as she will at her death.

SETUBAL, *St. Ubes*, or *St. Elbes*, a maritime city of Portugal, in the province of Estremadura, on the N. side of a bay of the same name, 18 m. S. E. of Lisbon; pop. about 15,000. It

stands in a valley, and is defended by a castle and forts. There are several squares and promenades, all superior to any in Lisbon; and the environs are interspersed with numerous picturesque villas and orange groves. Some of the churches are handsome; and among the convents are that of the Capuchin nuns, founded in 1480, and that of Arrabida, on a mountain 1,700 ft. high. The quays are broad, and the harbor is inferior only to that of Lisbon. The well known *St. Ubes* salt of commerce is manufactured here from the neighboring salt marshes of the river Sado, and shipped in immense quantities, principally to Scandinavian ports. Many of the inhabitants are engaged in fishing, and sardines are extensively exported, with oranges and other southern fruits, muscatel wines, and cork. Setubal is a place of great antiquity. It suffered severely from the earthquake of 1755.

SEVENTH DAY ADVENTISTS. See **SECOND ADVENTISTS.**

SEVENTH DAY BAPTISTS, a religious denomination known in England as *Sabbatarians*, where they have existed since the early part of the 17th century. In the United States they originated at Newport, R. I., in 1671. In 1818 the general conference rejected the name *Sabbatarians*, and adopted that of *Seventh Day Baptists*. Their views of baptism, communion, and doctrine generally, correspond with those of the Baptists. Their peculiarity is the observance of the seventh day of the week as the sabbath. They are scattered through Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Virginia, Ohio, Wisconsin, Indiana, Illinois, and Iowa, the greater number being in Rhode Island and New York. They have a missionary society supporting a prosperous mission at Shanghai, China; four academies, at Alfred and De Ruyter, N. Y., Shiloh, N. J., and Milton, Wis.; a sabbath tract and publication society, and an educational society which issues a weekly and a monthly periodical. The number of churches in 1874 was 83, and of members 8,237, an increase over the preceding year of 298.

SEVENTH DAY BAPTISTS, German. See **DUNKERS.**

SEVEN WONDERS. See supplement.

SEVEN YEARS' WAR, a contest involving the principal European powers from 1756 to 1763. The empress Maria Theresa, though forced in the treaty of Dresden (1745) to confirm Frederick the Great in the possession of Silesia, did not relinquish the hope of recovering it. She determined to secure a coalition that would crush the king of Prussia, and made active preparations for war. She courted the alliance of Louis XV., and by flattering Mme. de Pompadour gained over the French court. The

friendship between Great Britain and Austria was severed, and the system of European alliances was dissolved. George II., who was already involved in the French and Indian war, perceived that a continental conflict would at once expose his Hanoverian dominions to French invasion, and to protect himself against this danger he concluded a defensive treaty with Frederick the Great on Jan. 16, 1756. Maria Theresa now openly consummated the alliance with France (May 1). Elizabeth of Russia, whom Frederick had provoked by his satire, and Augustus III., king of Poland and elector of Saxony, who was eager to wipe out the disgrace of the previous war, joined the league; the mass of the German states followed; Sweden was gained by the hope of conquests in Pomerania; and a coalition was effected the most powerful that Europe had ever witnessed. The main events of the seven years' struggle in Europe have been described under FREDERICK II. Saxony, Bohemia, Silesia, and Brandenburg were the principal theatres of the war. Here the Prussian king, seconded by his brother Prince Henry, Schwerin, Keith, Seydlitz, the prince of Bevern, Zieten, Dohna, Lewald, and others, was opposed to the Austrian commanders Daun, Laudon, Browne, and Charles of Lorraine, and to the Russian generals Apraxin, Fermor, Soltikoff, and Tchernitcheff. In western Germany, where the incapable duke of Cumberland was defeated at Hastenbeck by the French under D'Estrées (July 26, 1757), and forced by Marshal Richelieu to sign the capitulation of Closter Seven (Klosterseven), the glory of the Prussian arms was sustained by Duke Ferdinand of Brunswick, who frustrated the efforts of Clermont, Contades, Soubise, and Broglie, and by victories like those of Orefeld (June 23, 1758) and Minden (Aug. 1, 1759). Still, Frederick was on the point of being overwhelmed by numbers, when the death of the empress Elizabeth (Jan. 5, 1762) and the accession of Peter III. changed the state of affairs. France, while lavishing her armies in the service of Austria, and her treasures in subsidizing a dozen allies, was compelled to witness the downfall of her colonial power. A French expedition under Marshal Richelieu had succeeded in conquering Minorca from the English, whom the first reverses in America and the fear of a French invasion had plunged into the utmost despondency; but the nation rallied, and under the guidance of the elder Pitt entered upon a remarkable career of success. Louisbourg was taken in 1758, Quebec fell in the following year, all Canada submitted, and Guadeloupe (1759), Martinique (1762), and other West India islands were conquered. Admiral Hawke won a brilliant victory over the French fleet in the bay of Quiberon in November, 1759, and the island of Belleisle, on the coast of France, was taken in June, 1761. Clive humbled the French power in India, and laid the foundations of a mighty empire. On the African coast the

English were equally successful. France, where Choiseul assumed the ministry in 1758, sought to restore her fortunes by a new alliance, and in 1761 concluded the family compact, which united the various branches of the house of Bourbon. A declaration of war between England and Spain followed. While Charles III., the Spanish king, unsuccessfully attacked Portugal, the English reduced Havana, where they obtained immense booty (August, 1762), and made themselves masters of the Philippines. The war was terminated by the treaty of Paris (Feb. 10, 1763) between England, France, and Spain, the preliminaries to which had been signed on Nov. 3, 1762, and by that of Hubertsburg (Feb. 15, 1763) between Prussia and Austria. Great Britain was aggrandized at the expense of the house of Bourbon, while the terms of the peace provided for a mutual restitution of conquests on the continent of Europe. Silesia remained in possession of Frederick. England retained her Canadian and a portion of her West Indian conquests, as well as those on the river Senegal, and acquired Florida from Spain, to whom as a compensation France ceded Louisiana. Martinique, Guadeloupe, and other islands (to which Santa Lucia was added), and Pondicherry were restored to France, and the privilege of the gulf of St. Lawrence and a portion of the Newfoundland coast was secured to French fishermen. In return Louis XV. agreed to dismantle Dunkirk on the sea side.—See Schäfer, *Geschichte des siebenjährigen Kriegs* (2 vols., Berlin, 1867-'8), and Ranke, *Ursprung des siebenjährigen Kriegs* (Leipsic, 1871).

SEVERN, next to the Thames the largest and most important river of England, rising in the S. part of Montgomeryshire, Wales, and falling into the Bristol channel, 10 m. S. W. of Bristol, after a generally N. E., S., and S. W. course of 210 m. Its most important tributaries are the Tern, Teme, Upper Avon, Wye, and Lower Avon. It is navigable 178 m. from its mouth, and the navigation has been extended by locks and canals. Below Gloucester extensive embankments have been raised to prevent inundation. At the mouth the tide rises 48 ft., and at Chepstow on the Wye 60 ft.

SEVERUS, Alexander. See ALEXANDER SEVERUS.

SEVERUS, Lucius Septimius, a Roman emperor, born of a family of equestrian rank near Leptis, Africa, April 11, A. D. 146, died in Eboracum (York), Britain, Feb. 4, 211. He studied law at Rome, became *advocatus fisci*, and afterward held many offices under Marcus Aurelius and Commodus, at Rome and in the provinces, gaining the favor of the people whom he governed, especially in Gallia Lugdunensis, by his integrity and moderation, combined with firmness. When Commodus was assassinated (192) Severus was commander of the army in Pannonia and Illyria; and after the brief reign of Pertinax and the sale of the empire by the prætorian guard to Didius Julianus, he was pro-

claimed emperor by his troops at Carnuntum, and marched upon Rome. No sooner had he appeared before the city (June, 193) than he was acknowledged emperor by the senate, and Julianus was deposed and killed. His first care was to disarm and banish the prætorian guard, and put to death all concerned in the murder of Pertinax. Clodius Albinus, commander of the Roman forces in Britain, and Pescennius Niger, in Syria, had each at the same time with Severus been proclaimed emperor by his army. The former, whom he most feared, Severus associated with himself as Cæsar; and against the latter, having distributed an immense largess to the troops, he marched within 30 days after his arrival at Rome, defeated his legate Æmilianus near Cyzicus, and Pescennius Niger himself near Nicæa, and again on the gulf of Issus, where Niger was slain. Byzantium held out for three years, when it was taken (196), devastated, and dismantled, Rome being thus deprived of its strongest bulwark against the Asiatic barbarians. Meanwhile Severus had crossed the Euphrates and subdued the border tribes. He next attempted to procure the assassination of Clodius Albinus, who, hearing of his intention, passed over into Gaul. Severus marched against him, and the armies, each 150,000 strong, met near Lugdunum (Lyons), Feb. 19, 197; after a terrible slaughter, during which Severus came near losing the battle and his life, Albinus was routed, and died by his own hand. Severus trampled the body under his horse's feet, ordered the head to be cut off and carried to Rome, whither he soon followed, and put to death the family of Albinus, as he had previously that of Niger, besides many senators and others. Soon after, marching against the Parthians, he took and plundered Ctesiphon and other cities, but was less successful against the Arabs. After spending three years more in settling the affairs of Arabia, Syria, and Egypt, he returned to Rome in 202, and gave shows and distributed money with unparalleled profusion, on occasion of his son Caracalla's marriage, and the completion of the 10th year of his reign. The next few years were passed in prosperous administration at Rome, but were disturbed by the discord and profligacy of his sons Caracalla and Geta, both of whom he associated with himself as Augusti. In 208, a war breaking out in Britain, he went thither with them. Caledonia was overrun by his soldiers to the northern extremity of the island; but 50,000 of them were destroyed by the climate and the attacks of concealed foes, and Severus retired southward and began building the wall known by his name. The Caledonians nominally submitted, but again rebelled, and he was preparing for a new campaign when he died.

SEVIER. I. A S. W. county of Arkansas, bordering on the Indian territory and bounded S. by Little river; area, about 825 sq. m.; pop. in 1870, 4,492, of whom 968 were colored. The surface is diversified and the soil mod-

erately fertile. The chief productions in 1870 were 1,919 bushels of wheat, 123,045 of Indian corn, 11,873 of sweet potatoes, 2,189 bales of cotton, 3,367 lbs. of tobacco, and 3,761 of wool. There were 757 horses, 363 mules and asses, 1,472 milch cows, 2,906 other cattle, 2,507 sheep, and 8,658 swine. Capital, Lockesburgh.

II. An E. county of Tennessee, bordering on North Carolina and traversed by French Broad and Little Pigeon rivers; area, 520 sq. m.; pop. in 1870, 11,028, of whom 533 were colored. Much of the surface is mountainous, and the soil along the streams is fertile. Limestone and iron ore abound. The chief productions in 1870 were 63,483 bushels of wheat, 260,214 of Indian corn, 42,460 of oats, 13,997 lbs. of tobacco, 16,109 of wool, 79,135 of butter, 15,528 of honey, and 16,588 gallons of sorghum molasses. There were 1,954 horses, 2,264 milch cows, 3,950 other cattle, 9,578 sheep, and 13,088 swine. Capital, Sevier-ville. **III.** An E. county of Utah, bordering on Colorado, and intersected by the Green and Grand rivers; area, about 7,000 sq. m.; pop. in 1870, 19. The W. part is crossed by the Wahsatch mountains, and watered by Sevier river. Capital, Richfield.

SÉVIGNÉ, Marie de Rabutin-Chantal, marquise de, a French epistolary writer, born in Paris, Feb. 6, 1626, died at Grignan, April 18, 1696. Left an orphan at the age of six, she was brought up by her maternal grandfather, and afterward by her uncle, the abbé de Coulanges, whom she used to style in her letters *Bienbon*. She received lessons and advice from Chapelain and Ménage, who taught her Latin, Spanish, and Italian. As soon as she appeared in society, she was greatly admired on account of her beauty, wit, and wealth. In 1644 she married the marquis Henri de Sévigné, a nobleman of Brittany and a relative of the Retz family, who in 1645 was appointed governor of Fougères. Owing to her husband's family relations, she was involved in the civil troubles of the Fronde, and became acquainted with the duchesses of Longueville and Chevreuse. Her husband was killed in a duel in 1651, and she devoted herself to the education of her son and daughter. Mme. de Sévigné received the homage of many distinguished personages, including the prince of Conti, Marshal Turenne, the count de Bussy (her cousin), and Fouquet. Her letters to her daughter, the marquise de Grignan, which are admired for their vivacity, delicacy, and wit, were not intended for publication, and they were not printed till 30 years after her death (1726). One of the most complete editions is by Regnier, included in *Les grands écrivains de la France* (14 vols., 1862-'6). A selection from the English editions has been edited by Mrs. S. J. Hale (12mo, New York, 1856).—See Walckenaer, *Mémoires touchant la vie et les écrits de Mme. de Sévigné* (5 vols. 12mo, Paris, 1842-'52), and "Madame de Sévigné, her Correspondence and Contemporaries," by Countess de Puliga (2 vols. 8vo, London, 1872).

SEVILLE (Sp. *Sevilla*). I. A S. W. province of Spain, in Andalusia, bordering on Badajoz, Cordova, Malaga, Cadiz, and Huelva; area, 5,295 sq. m.; pop. in 1870, 515,011. The northern portion is traversed by the Sierra Morena, and the southern by the Sierra Ronda, with some peaks of considerable elevation; the remainder of the province mainly consists of vast and fertile plains, drained by the Guadalquivir and its tributaries, the largest of which are the Genil, Viar, and Huelva. The climate is extremely hot in summer, but very salubrious. Agriculture is well advanced, and the vine and olive are particularly abundant. There are large numbers of cattle, horses of superior breed, mules, sheep, goats, and swine. Among the mineral products are silver, iron, copper, and lead, with coal, marble, and limestone. Wines and oil of superior quality are produced; and there are manufactories, chiefly at the capital, of silk, woollen, and linen fabrics, soap, leather, brandy, hats, porcelain, common earthenware, leather, &c. The principal town besides the capital is Ecija. II. A city (anc. *Hispalis*), capital of the province and of Andalusia, on the left bank of the Guadalquivir, 62 m. N. N. E. of Cadiz, and 242 m. S. W. of Madrid; pop. (including its seven suburbs) about 115,000. It is situated in a delightful plain, and surrounded by Moorish walls with 66 towers and 14 gates. In 1864 it had 564 streets, mostly

magnificent colonnades and courtyards, paved with porcelain tiles or marble and embellished with fountains. The cathedral, one of the largest and finest in Spain, exquisitely decorated within and without, was completed in 1519, on the site successively occupied by the temples of Astarte and Salambo, and the ancient mosque of Seville. Although repeatedly despoiled, it still contains some of its finest pictures by Murillo and other masters. The main tower, the Giralda, erected in 1196 as the chief muezzin tower of the ancient mosque, was at first but 250 ft. high; but in 1568 was added a superb filigree belfry surmounted by a bronze figure of "Faith," and the present height is about 350 ft. The cathedral has one of the largest organs in the world, and contains the tombs of St. Ferdinand, who conquered the city from the Moors, Queen Beatrice his first wife, Alfonso the Wise, and other celebrities. Attached to the *sagrario* or parish church, contiguous to the cathedral, is a library of about 18,000 volumes, the gift of Fernando Columbus, the son of Christopher, and containing several manuscripts by him and his father. The city has a large number of other parish churches, chapels, convents, and nunneries. The benevolent institutions are also numerous. Among the other edifices of note are the *alcázar* or Moorish castle, in many respects equal to the Alhambra of Granada; the archiepiscopal palace; the *casa de Pilato*, so called from a reputed resemblance to Pontius Pilate's house at Jerusalem, and now the palace of the duke of Medina-Celi; the city hall and other government buildings; the court house, mint, exchange, custom house, and tobacco factory. The *torre de oro* or tower of gold, long the storehouse for the treasures from America, is said to have been built by the Romans. The bull ring, commenced in 1760, but still unfinished, accommodates 11,000 spectators. The university, founded in the beginning of the 16th century, has a good collection of pictures and sculptures, museums of chemistry, physics, mineralogy, and zoölogy, and a botanical garden. Seville has also a school of fine arts, colleges of law, medicine, and commerce, a nautical academy, and a large number of other schools, many of which are for females alone. In the grand tobacco factory are employed 3,000 women, chiefly from the Canaries, and 600 men; and brass cannon, small firearms, saltpetre, and gunpowder are made in the ordnance foundry. Seville formerly carried on a large portion of the trade with the new world. This business was in the early part of the 18th century transferred to Cadiz in consequence of the silting up of the Guadalquivir, which rendered it unnavigable by vessels of over 100 tons. The staple articles of export are oil, oranges, wine, silk, leather, quicksilver, copper, and lead.—Seville was called Sephela by the Phœnicians, *Hispalis* by the Romans, and *Ishbiliyah* by the Moors. It was captured in 45 B. C. by Julius Cæsar, who made it a Ro-

The Giralda.

narrow and tortuous, but well lighted, and 62 public squares. Many of the houses are remarkable for architectural beauty, and have

Interior of the Alcázar of Seville.

man colony, patronizing it in opposition to Cordova, which had espoused the cause of Pompey. When the Goths invaded the country they made it their seat of power, but in the 6th century the court was removed to Toledo. It was in the hands of the Moors from 711 till 1248, and under them attained great splendor, and a population of 300,000. In 1248 Ferdinand III. of Castile and Leon took it after a long siege, and made it the capital of those united kingdoms, which it remained until the reign of Charles V. A treaty was concluded at Seville in 1729 between Spain, France, and England. The city surrendered to the French under Soult in 1810, when the inhabitants were cruelly treated, the plunder and money extorted from them being estimated at \$30,000,000. They evacuated it in August, 1812, when the English entered the town. It was besieged by Espartero in July, 1843.

SÈVRES, a town of France, in the department of Seine-et-Oise, on the left bank of the Seine, 6 m. S. W. of Paris; pop. in 1872, 7,096. It stands in a valley between the hills of Meudon and St. Cloud, and the main street is of great length, being traversed by the Versailles road. The celebrated porcelain factory was removed hither in 1756 from Vincennes, and in 1760 became the sole property of Louis XV. (See *POTTERY AND PORCELAIN*, vol. xiii., p. 785.) Connected with it is a museum, and in 1875 a school of mosaics was established. There are also manufactories of shawls, cordage, leather, and chemical substances, and various chemical arts are carried on.—Sèvres was occupied by the Germans Sept. 19, 1870, bombarded by the French Oct. 5, and attacked by the troops of the commune April 4, 1871.

SÈVRES, Deux, a W. department of France, in the old provinces of Poitou and Angoumois, bordering on Maine-et-Loire, Vienne, Charente, Charente-Inférieure, and Vendée; area, 2,317 sq. m.; pop. in 1872, 331,243. A chain of hills which have a mean height of 450 ft. traverses the department S. E. and N. W., dividing it into two distinct portions. The Sèvre-Nantaise and Sèvre-Niortaise, which rise in the department and give it its name, flow respectively N. W. to the Loire at Nantes and W. to the Atlantic, passing Niort. The Thouet and several other small rivers also have their sources here. The department is traversed by seven canals. Iron, rock crystals, and saltpetre are found. The vineyards in the S. W. part produce good brandy and white wines. There are manufactories of woollen, linen, and cotton goods, leather, earthenware, brandy, cutlery, and paper. It is divided into the arrondissements of Bressuire, Melle, Niort, and Parthenay. Capital, Niort.

SEWARD. **I.** A S. E. county of Nebraska, intersected by the Big Blue river and its forks; area, 576 sq. m.; pop. in 1875, 6,601. The surface is undulating and the soil productive. It is traversed by the Midland Pacific railroad. The chief productions in 1870 were 58,579 bushels of wheat, 58,637 of Indian corn, 31,620 of oats, 18,488 of potatoes, 35,601 lbs. of butter, and 5,205 tons of hay. There were 1,214 horses, 718 milch cows, 1,161 other cattle, 509 sheep, 1,296 swine, and 3 saw mills. Capital, Seward. **II.** An unorganized S. W. county of Kansas, bordering on Indian territory; area, 720 sq. m. It is watered by affluents of the Cimarron river. The surface consists of rolling prairies.

SEWARD, Anna, an English authoress, born at Eyam, Derbyshire, in 1747, died in Lichfield, March 25, 1809. At nine years of age she could repeat the first three books of "Paradise Lost." At Lichfield, where the greater part of her life was passed, she became intimate with Dr. Erasmus Darwin, of whom in 1804 she published a memoir, in which she lays claim to the first 50 lines of his "Botanical Garden." Her poetical works consist of "Louisa," a metrical novel (1782), and "Sonnets" (1799). Her elegies on Captain Cook and Major André had great celebrity. She was called by her contemporaries of the Della Cruscan school "the swan of Lichfield." She bequeathed a mass of manuscript poetry and correspondence to Sir Walter Scott, which he edited in 1810. Constable also published six volumes of her correspondence (1811).

SEWARD, William Henry, an American statesman, born in Florida, Orange co., N. Y., May 16, 1801, died in Auburn, N. Y., Oct. 10, 1872. He graduated at Union college in 1820, having passed six months of his senior year in teaching in Georgia, and was admitted to the bar in 1822. He commenced practice in Auburn, where in 1824 he entered upon political life by preparing an address for a republican convention, announcing an opposition to the "Albany regency," as the leaders of the democratic party of New York were then styled, which was continued until crowned with success in 1838. In August, 1828, he presided over a young men's convention in New York, called to favor the reelection of John Quincy Adams to the presidency, and on his return home was tendered a nomination as member of congress, which he declined. In 1830 he was elected to the state senate as an anti-mason by a majority of 2,000, although the district had given a large adverse majority the preceding year. He originated an opposition to corporate monopolies which has since ripened into a system of general laws. In 1833 he made a rapid tour of Great Britain and a portion of the continent, and contributed a series of letters to the Albany "Evening Journal." In 1834 he was the whig candidate for governor, and was defeated by W. L. Marcy; but in 1838 he was elected governor by a majority of 10,000 over Gov. Marcy. Among the measures to which he directed his attention were the extension of public education, the prosecution of the public works, including the enlargement of the Erie canal, and the removal of the legal disabilities imposed on foreigners. A prominent feature of his administration was his effort to secure the diffusion of common school education among children of every class, especially those in large cities and of foreign parentage, advocating an equal distribution of the public funds among all schools established with that object. Amid much opposition he exerted all his influence in favor of a reform in the courts of law and of chancery, preparing the way for the radical changes effected in the constitution of

1846. The geological survey of the state, the perfection of the general banking system, and the establishment of a lunatic asylum were also measures of his administration. Imprisonment for debt was entirely abolished, the anti-rent rebellion was subdued, and every vestige of slavery was cleared from the statute books. In a controversy between Gov. Seward and the executive of Virginia on the application of the latter for the return of two seamen charged with abducting slaves, Seward maintained that no state could force a requisition upon another state founded on an act which was only criminal by its own legislation, and which, compared with general standards, was not only innocent, but humane and praiseworthy. The correspondence, known as "the Virginian controversy," was widely published. Mr. Seward was reelected in 1840. On retiring from office (Jan. 1, 1843) he resumed the practice of law, first in the state courts, and afterward acquiring a lucrative share of patent causes in the courts of the United States. He occasionally appeared in criminal cases where persons were, as he thought, unjustly accused, when he not only gave his best efforts gratuitously, but sometimes furnished large sums for a proper defence. His arguments in the cases of Van Zandt, charged with harboring fugitive slaves in Ohio, of Freeman, charged with murder, and of 50 citizens of Michigan indicted for conspiracy, hold a high rank in the records of criminal trials. In 1844 Mr. Seward entered with energy into the presidential contest in behalf of Henry Clay, and again in 1848 in support of Gen. Taylor. In February, 1849, he was elected United States senator. On the meeting of congress in December following, the members from the south, apprehending the adoption of an anti-slavery policy, took ground in opposition to Gen. Taylor's administration, and Mr. Seward soon became the leader of the administration party. In his subsequent speeches he avowed a determination to make no further concessions to the slave power, and was denounced as a seditious and dangerous agitator. In a speech on the admission of California into the Union, March 11, 1850, he used the following language: "It is true, indeed, that the national domain is ours. It is true, it was acquired by the valor and with the wealth of the whole nation. But we hold, nevertheless, no arbitrary power over it. We hold no arbitrary authority over anything, whether acquired lawfully or seized by usurpation. The constitution regulates our stewardship; the constitution devotes the domain to union, to justice, to defence, to welfare, and to liberty. But there is a higher law than the constitution, which regulates our authority over the domain, and devotes it to the same noble purposes. The territory is a part, no inconsiderable part, of the common heritage of mankind, bestowed upon them by the Creator of the universe. We are his stewards, and must

so discharge our trust as to secure in the highest attainable degree their happiness." The phrase "higher law," thus applied to the law of God, was the subject of much excited comment in the senate and in the public press, and was afterward urged as a ground of reproach by the political enemies of Mr. Seward. The death of President Taylor in July, 1850, and the accession of Vice President Fillmore, brought the conservative wing of the whig party into prominence; but Mr. Seward still maintained his position as a leader on the anti-slavery side. Besides his speeches on the compromises of 1850, he delivered several others on the commercial and industrial relations of the country. His speeches on the repeal of the Missouri compromise and the admission of Kansas, like those on the compromises of 1850, were widely circulated. In 1858 he made a speech at Rochester, in which, after alluding to the constant collision between the systems of free and slave labor in the United States, he said: "It is an irrepressible conflict between opposing and enduring forces, and it means that the United States must and will, sooner or later, become either entirely a slaveholding nation, or entirely a free labor nation." The southern secession threatening during the last session of the 36th congress (1860-'61), Mr. Seward in the senate expressed his views on "the state of the Union" in two speeches, in which he said: "I avow my adherence to the Union with my friends, with my party, with my state, or without either, as they may determine; in every event of peace or war, with every consequence of honor or dishonor, of life or death." He declared also in conclusion: "I certainly shall never directly or indirectly give my vote to establish or sanction slavery in the common territories of the United States, or anywhere else in the world." Mr. Seward's second term closed with the 36th congress, March 4, 1861. He had been reelected in 1855 under circumstances of peculiar interest. He was strenuously opposed both by those who disliked his uncompromising resistance to the slave interest, and by those who could not tolerate his opposition to the "American" party, at that time a rising power throughout the Union. The whig party having adopted in 1852 a platform approving of the slavery compromises of 1850, and nominated Gen. Scott for the presidency, Mr. Seward declined to sustain the platform, while he yielded his support to the candidate. In the presidential canvass of 1856 he was very active in behalf of Col. Fremont, the republican candidate. In 1859 he made a second visit to Europe, and extended his travels to Egypt and the Holy Land. In 1860, as in 1856, a large portion of the republican party favored his nomination for the presidency. In the convention, on the first ballot, he received 173½ votes, Mr. Lincoln, the next highest, 102—necessary for a choice, 233. Lincoln having been nominated, Seward

actively canvassed the western states in his behalf. Lincoln tendered the chief place in his cabinet to Mr. Seward, and on March 4, 1861, he entered upon the duties of secretary of state. Secession was then imminent, but Seward apparently failed at first to apprehend the magnitude of the movement. He declined (March, 1861) to negotiate with confederate commissioners, but believed that the difficulties of the two sections could be settled without recourse to arms; and he favored as a peace measure the evacuation of Forts Pickens and Sumter. During the entire war his management of foreign affairs was eminently politic and effective. Conspicuous among these efforts were his conduct in the Trent affair (November, 1861); his declining the proposal of France to unite with Russia and Great Britain to mediate between the federal government and the confederates; his course in respect to the French invasion of Mexico; and his thorough reorganization of the diplomatic service abroad, so that by the American representatives, as well as by his own despatches, the real issues at stake in the civil war were constantly made prominent to foreign governments. His diplomatic management during this critical period more than once kept the country from involvement in a foreign war. On Lincoln's election to a second term Seward continued as secretary of state. Early in the spring of 1865 he was thrown from his carriage, and his jaw and one arm were broken. While he was confined to his bed by these injuries, on the night of the assassination of Lincoln, April 14, one of the conspirators penetrated to Seward's room and struck him several times with a knife, and also severely wounded Frederick W. Seward, who came to his father's rescue. The assassin escaped from the house, but was soon arrested, and was hanged with other conspirators, July 7. Mr. Seward's recovery was slow and painful; but as soon as he was able he resumed the duties of his office under President Johnson, becoming unpopular with a large portion of his party from his support of the president's reconstruction policy. In March, 1869, he retired from public life, and soon after made an extended tour through California and Oregon, and went to Alaska, which had been acquired during his secretaryship and mainly through his efforts. In August, 1870, accompanied by members of his family, he set out upon a tour around the world, returning to Auburn in October, 1871. He was everywhere received with the greatest distinction, and the results of his observations were embodied in "William H. Seward's Travels around the World," edited by his adopted daughter, Olive Risley Seward (8vo, New York, 1873).—Mr. Seward contributed a historical essay, entitled "Notes on New York," to the great work on the natural history of the state, to which it forms the introduction. In the senate he delivered eulogiums on Clay, Webster, Clayton, Rusk, and Broderick. In 1849 he prepared a life of John

Quincy Adams in a popular form, which had an immense sale. He also wrote a biography of De Witt Clinton, an abstract of which he prepared for this Cyclopædia. "The Works of William H. Seward" (4 vols. 8vo, New York, 1853-'62) include a biographical memoir and historical notes, edited by George E. Baker. Most of his public orations have been printed separately; the latest is "Speech at Sitka, Aug. 12, 1869." See also "Review of Mr. Seward's Correspondence of 1862," by William B. Reed (Philadelphia, 1862); "The Life, Character, and Services of William H. Seward," a memorial address before the New York legislature, April 18, 1873, by Charles Francis Adams (New York, 1873); and "Lincoln and Seward," remarks on Mr. Adams's address, by Gideon Welles (New York, 1874).

SEWELL. I. William, an English clergyman, born in the isle of Wight about 1805, died at Leachford hall, near Manchester, Nov. 14, 1874. He was the son of a solicitor, was educated at Harrow and Oxford, and became fellow of Exeter college and incumbent of Carisbrook castle chapel, isle of Wight. He was public examiner in the university from 1836 to 1841, and in 1852 was appointed principal of St. Peter's college at Radley. He was a supporter of the tractarian movement. He published "Hora Philologica" and "Conjectures on the Structure of the Greek Language" (1830); "Sacred Thoughts in Verse" (1831; 2d ed., 1842); "Parochial Sermons" (1832); "Christian Morals" (1840; new ed., 1849); "Introduction to the Dialogues of Plato" (1841); "Christian Politics" (1844); "The Agamemnon of Æschylus," translated (1846); literal and rhythmical translations of "The Georgics of Virgil" (1846) and "The Odes and Epodes of Horace" (1850); and "Christian Vestiges of Creation" (1861).

II. Elizabeth Missing, an English authoress, sister of the preceding, born in the isle of Wight in 1815. Her first publication was "Amy Herbert" (1844), a high church religious novel. Among her later works are: "Gertrude" (1847); "Experience of Life" and "Journal of a Summer Tour on the Continent" (1852); "Katherine Ashton" (1854); "Ivors" (1856); "Ursula, a Tale of Country Life," "Clove Hall," "Earl's Daughter," and "Margaret Percival" (1858); "History of the Early Church" (1859); "Impressions of Rome, Florence, and Turin" (1862); "Isabel Grey" and "The Poor Brother" (1863); "Homely Ballads and Stories in Verse" (1865); "Rose of Cheriton, a Ballad" (1866); and several religious works and histories of Greece and Rome for the young.

SEWELLEL, a North American rodent of the genus *aplodontia* (Rich.), so called from the simple structure of the molars, apparently connecting the beaver with the squirrels through the spermophiles. It resembles the prairie dogs in the hairy and obtuse nose, fore feet with five claws, distinct ears, very short tail, and the flattened outline of the skull; but the

rootless molars and the absence of post-orbital process bring it near the beaver. The fore claws are much larger than the hind ones,

Sewellel (*Aplodontia leporina*).

even the short thumb having one; the soles and heels naked; the mouth is rather small, the lips thick, and cheek pouches absent; the incisors are strong, flat, without grooves, and yellow, and the molars $\frac{1}{2}$ - $\frac{5}{8}$, prismatic, the anterior very small; the bony orbits very large, and the cranial cavity small; the descending branch of the lower jaw is twisted so as to be horizontal behind, and its lower angles are extended inward as far as the molars, the whole jaw being very strong. The only described species of the genus is the *A. leporina* (Rich.), about the size of a muskrat, with a short, thick, and heavy body; the color is reddish brown, grayish plumbeous below; the eyes are very small, the whiskers long and stiff, the ears rounded and covered with hair, and the tail much flattened; the fur is dense and soft, with longer bristly dark hairs interspersed; the limbs are short and robust; mammae six, the interior two between the fore legs; the length is 16 in., of which the head is $3\frac{1}{2}$ in. and the tail $1\frac{1}{2}$ in. It is found on the N. W. coast, in Washington territory, in Oregon, and in California, in timber lands near the coast. They form small societies, living in burrows, and feeding on vegetables; the natives make robes of the skins.

SEWERAGE, a system of drainage under the streets of towns for carrying off the surface waters and the liquid refuse matters from houses. The necessity of underground channels of this character to the comfort and health of thickly populated places was well understood by the ancient Romans, who at a very early period adopted a regular system of drainage in their famous sewers. (See *CLOACÆ*.) These included not merely the spacious subterranean vaults by which the drainage of the pestilential marshes about the city was effected, but also the wooden pipes, clay tubes, or drains of whatever kind by which the impurities were conveyed from the houses into the main conduits. An elaborate system of sewerage has recently been discovered in con-

nection with the Colosseum. So completely was the city underlaid by these passages, that it was designated by Pliny as *urbs pensilis*, a city supported upon arches. The *avaskara mandira* (filth temple) of the ancient Hindoos was beyond doubt connected with channels and receptacles for its accumulations. The great canal system of Egypt, executed under Rameses I. and his successors, served extensive sewerage purposes; and probably also the magnificent canals of Assyria and Babylon, fed by the Tigris and Euphrates. The ancient Chaldean tomb mounds possess great interest on account of their system of drainage. Long shafts of baked clay extend from the surface of the mound to its base, composed of a succession of rings 2 ft. in diameter and about 1½ ft. wide, joined together by thin layers of bitumen. (See Rawlinson's "Five Ancient Monarchies," vol. i., p. 89.) The recent discoveries of Dr. Pierotti among the ruins of Jerusalem have shown that the ancient city contained a complex and perfect system of aqueducts, drains, and reservoirs. The preservation of many of the aqueducts is owing to the fact that they were excavated in the solid rock, and have not been affected by the demolition of the structures above. It appears that the pool of Siloam received the washings of the temple, and the liquid was used for the purpose of irrigating the king's gardens. The discoveries clearly show that the inhabitants of Jerusalem were fully aware of the necessity of speedily removing all decomposable refuse matter.—The system of sewerage of Paris has during the last half century been made among the finest in the world. Previous to the 14th century, Paris being walled only on the south, the drainage of the faubourgs St. Germain and St. Marceau was poured into the Bièvre; but when this district was surrounded by ditches about 1356, in the reign of King John, the sewers of the quarter St. Germain-des-Prés were turned into these ditches, and they have since taken the same course, being carried by the vaulted sewer which starts from near the *école de médecine*, and empties into the Seine below the *palais des arts*. On the opposite bank an open sewer was covered over in the reign of Charles VI. by Hugues Aubriot, and hence he is said to have commenced the system of covered sewers in Paris. The open sewer of St. Catharine was very offensive to the inhabitants of the *palais des tournelles*, and as a consequence Francis I. bought the site of the Tuileries. As late as 1663, in the reign of Louis XII., there were only 1,207 toises of covered sewers in Paris, and 4,120 toises of open sewers or ditches. The sewer formed by the ancient rivulet of Ménilmontant, then and now called the *grand égout de ceinture*, was not walled and covered till 1740. In 1805 Napoleon authorized necessary repairs and the extension of the covered sewers of Paris. In 1806 there were about 23,000 metres of covered sewers, but in 1862 they amounted to

about 226,000; at present (1875) the total length of covered sewers is about 400,000 metres, or nearly 250 m. To organize the great system of sewerage, Paris was divided into five basins, of which three are on the right and two on the left bank of the Seine. Six principal galleries cut the city at right angles, and receive 15 secondary galleries, and these in turn numerous minor galleries. Besides these galleries, the old grand sewer, the *égout de ceinture*, serves as a collector, into which the others empty. This grand sewer now starts from the rue des Coutres-Saint-Gervais, follows the rues Vieille-du-Temple and Filles-du-Calvaire, crosses the boulevards, follows the rue des Fossés-du-Temple, traverses the lower end of the boulevard Prince Eugène, continues its course through the rues du Château-d'Eau, des Petites-Écuries, Richer, de Provence, and de Saint Nicolas-d'Antin, and falls into the general collector at Asnières, under the boulevard Malesherbes. Formerly it emptied into the Seine at Chaillot. The principal galleries on the left bank are: 1, that along the line of quays; 2, that which follows the boulevard Saint-Michel; and 3, the vast subterranean canal which receives the Bièvre. These sewers also fall into the general collector at Asnières, under the place de la Concorde, crossing the Seine by means of a reversed iron siphon over a yard in diameter and 217 yards long, entering the river about 6 ft. below low-water mark. In many of the galleries there are railways, on which cars are run in cleaning the sewers, and also for carrying visitors. The water and gas mains are also carried in the galleries covering the principal sewers.—In England sewer commissioners were appointed in the reign of Henry VI., but their powers were restricted to surface drainage and sea walls, the subject of municipal sewerage being left principally to local commissions, and in some of the cities to corporations empowered by special acts of parliament. The drainage of London was provided for by legislative enactments commencing in 1225, and the whole subject was thoroughly revised by Sir Thomas More in the celebrated "bill of sewers," passed in 1531. The use of the sewers of London, even up to the present century, was limited to the removal of the waters that ran in the gutters of the streets, including those thrown out from the houses; and in the reign of George III. an act was passed prohibiting the discharge of other matters into them under penalty of a fine. Every house was provided with a cesspool, and this was occasionally discharged by the night carts which conveyed away the offensive matters. Upon the gravelly soil to which the city was then limited this answered very well; but its extension over the more impervious clay beds, and the introduction of abundant supplies of water into every house, followed by the invention of water closets, led to a new use of the sewers, and to various results not at all contemplated in their original

construction. The refuse matters of the cess-pools, instead of being transported into the country to serve as manure, were turned into the river Thames, polluting its waters, while the sewers themselves in the lower parts of the city were incompetent to discharge the increased burdens, and the ventilating flues through the streets became avenues of the most poisonous gases. A reconstruction of many of the sewers upon a larger scale became necessary, and they were laid out upon a regular system, coming down to the river from each side for a distance of 6 m. along its course. Their total length exceeded 2,000 m., and when they were completed London was regarded in 1855 as one of the best drained cities in the world. The principal sewers were of extraordinary dimensions, several being from 12 to 14 ft. high and 6½ ft. wide. Notwithstanding the great scale of this drainage system, the most serious difficulties were experienced in its operation. The outlets of the sewers, in order to get sufficient fall for discharge, were placed but little above low-water mark, the surface of some portions of the city itself being below high-water mark. Consequently the sewers were closed by the tide except at low water, and the gaseous contents of the sewage turned back into the city and up the drains into every street and house. The discharge moreover taking place only about the time of lowest water, the accumulated contents of the sewers were kept up the river until the ebb, and when at last carried down the stream they were replaced by the same amount of fresh filth. Foul banks of black mud, from which most offensive odors emanated when laid bare at low tide, collected along the banks and in the shallow parts of the river. In 1858 it was decided to adopt some active measures for the abatement of the nuisance. It was attempted to disinfect the sewage by discharging every day during the warm weather immense quantities of lime and chloride of lime into the river. The quantities of these thus thrown in in the summer of 1859 amounted to 110 tons of lime and 12 tons of the chloride every day, at a weekly cost of about £1,500; and in that season £20,000 more were also expended in flushing the sewers in order to aid in expelling their contents at extreme low water. Plans were also sought for from scientific and practical men by which the serious difficulties encountered might be permanently overcome; and at last one submitted by Mr. Bazalgette, chief engineer of the board of works, was adopted and executed. The main feature of this plan consists in a series of three grand parallel main sewers at different levels and distances from the river, and on each side of it, which cross the old sewers and outfalls at right angles and intercept the contents of the old system, conveying them on the north of the Thames down the river to Barking, a distance of 7 m., and on the south side to Crossness in the Erith marshes, 7½ m. At this point

the sewage is received in enormous reservoirs, which principally discharge at favorable conditions of tide into the Thames; but a portion is used in making what is called "native guano" by the "A, B, C" process. The work of constructing these great intercepts, pumping stations, &c., was immense; the intercepting sewers alone, 82 m. in length, cost £4,250,000, which was raised by a third rate levied on the metropolis, yielding £180,262 per annum, principal and interest to be paid off in 40 years. It is estimated that the total cost of these great works will not be far from £30,000,000. Notwithstanding the great improvements that have been effected in England, serious defects still exist affecting the water supply of London, from sewage outfalls above the city, but which were being remedied in 1875.—In America, sewer construction has both an ancient and a modern history. The works of the mound builders prove them to have been expert in the building of reservoirs, aqueducts, and conduits; and various places between the north-west and Central America exhibit remains of their sewer constructions. The modern history of sewers in America is not marked by any special achievements, the sewer systems of her principal cities being the result of rapidly increasing necessity. As a rule, therefore, the sewers of the cities have been built piecemeal and rarely on a far-sighted plan, and generally discharge into the nearest available body of water.—The construction of sewers depends, as to material, size, shape, &c., upon the uses they are to serve, and the conditions under which they must be built, embracing the consideration of area to be sewered, its geological and topographical characters, the amount of rainfall, the water supply, the present and prospective population, and the disposal of the sewage. The difficulties encountered are in part the character of the earth, this being often so soft as to demand artificial supports for the pipes and sides of trench, or so hard as to require expensive excavation, the difficulty of securing sufficient fall, and that of providing for varying degrees of foulness in street wash, and securing safe escape for sewer gases. For cleaning purposes large man-holes are now depended upon, together with facilities for flushing. The form depends upon the amount of surface water, of manufacturing waste and excrement, and of subsoil water. If the sewage contains little solid matter, a flat or obtuse oval bottom will answer; but it is found that less fluid matters will be more efficiently discharged by an egg-shaped oval, which secures a greater depth and velocity of flow. An important change has of late years been made by the substitution, where the drainage is comparatively small, of small earthenware pipes for large brick and stone sewers, whereby leakage and earth contamination have been reduced. A difficulty attending their use is the removing of sections for repairs. The *cloaca maxima* of Rome and the great sewers

of Paris are built of cut stone, as were some of the conduits of the mound builders. The great main drainage works of London are cylindrical sewers of brick. The system of Capt. Liernur, now so highly lauded and being adopted in Europe generally, has its pipes all of riveted wrought or cast iron. Sewers are generally laid along the middle of the street and at depths according to the grades. At many street corners "catch pools" are built of brickwork, which, covered by open gratings, receive the wash of the street, retaining in the bottom the mud and sand and discharging the water into the sewer. In towns having districts whose surface is scarcely above high tide, the principle of interception requires attention from the engineer. Intercepting sewers receive the surface water, and often also the sewage, and divert it from the common sewer which passes to the lower districts. In towns where the sewage is pumped from the lower districts to higher levels on account of tide-locked sewers, the system of interception becomes of great importance and greatly reduces the cost of drainage. This is well understood in the great drainage works in the fen districts of England, where large areas are entirely surrounded by intercepting drains, which lead the water off by gravitation. The great intercepting sewers of London, which have been mentioned, have been constructed to convey rainfall at the rate of a quarter of an inch in depth over the whole area drained every 24 hours, at the time the maximum flow of sewage is being discharged. When the flow in a sewer does not carry off the solid contents, it is convenient to clean it by washing it out, or "flushing" as it is technically termed. The operation is performed by letting in water at the higher levels, or by retaining the sewage in sections by means of gates, and, when the portion below has become partly empty and that above nearly full, allowing the collection by its gravity to sweep away accumulations below. The grounds occupied by the annual fair at Nizhni Novgorod, Russia, have sewers built of cut stone arranged in regular streets. They are lofty and well ventilated, and are entered by stairways through towers placed at intervals. They are flushed every day with water pumped from the Volga.—The ventilation of sewers is a subject of great importance in a sanitary point of view. The effluvium from the ventilating holes in pavements has been found to taint meat in butchers' stalls in their vicinity, to avoid which connections have been made with the chimneys of manufacturing establishments. It is not improbable that the solution of the problem will be in the erection of special chimney stacks. The relative efficiency of deodorizers has received attention. In 1858 the commissioners of London sewers reported that wood charcoal has a power of deodorizing currents of foul gases which is not much diminished by long use. The comparative cost of disinfectants to purify a given amount of sewer

age in a uniform condition, made previous to the report, is shown in the following table:

Boghead charcoal (coke), 1 ton.....	\$3 00
Nitric acid.....	8 50
Black oxide of manganese.....	9 25
Chloride of lime.....	10 75
Peat charcoal.....	11 00
Animal charcoal.....	16 75
Bichloride of mercury.....	18 00
Impure chloride of zinc in damp powders.....	26 00
Chloride of zinc in solution (Sir William Burnett's).....	37 00
Sulphate of copper.....	39 00

Other sulphates, as well as a number of other substances sometimes employed as disinfectants, proved ineffectual even in very large quantities to produce complete deodorization; but arsenious acid, creosote, and carbolic acid were found to possess great deodorizing power. Baldwin Latham has devised a combination of man-hole, street-water, and dirt catch with overflow pipe, and a charcoal ventilator protected from wet, which has been put in use in London with fair results. The gases principally found in sewers are carbonic acid, sulphuretted and carburetted hydrogen, ammonia, nitrogen, and fetid organic vapor; but it is only in the most unfavorable localities that the permanent gases are in sufficient quantity to produce of themselves bad effects. It is the poisonous germs contained in the accompanying organic vapor, and which may not have any very offensive or at least powerful smell, that confer on "sewer gas" its most deleterious properties. To prevent the entrance of sewer gas into houses is a problem which presents many practical difficulties. Various forms, of traps are placed at the discharge of the house pipe into the sewer, and also in the water closets and beneath the wash bowls. In the discharge into the sewer the pipe usually dips beneath the surface of the water in a receptacle which empties into the sewer. In water closets a "sealing pan," as it is called, holds water in its cavity when its rim is horizontal, the level of which is above the lower rim of the hopper. The joints of the hopper at the upper rim being made tight, no gas can escape into the room. The waste pipe below the hopper has a syphon crook, which when filled with water prevents the escape of gas from the pipe below. Other kinds of closets, which involve some additional expense, are preferred. A pump closet, used upon ships and below the water line, is modified for house purposes, and made to exhaust the hopper and force the contents out of the soil pipe.—*Disposal of Sewage.* This is one of the vexed and unsettled problems of the day, both in an economical and a sanitary point of view, and embraces the question of utilization of sewage, which also includes many plans, none of which have been confirmed as satisfactory. It is the opinion of many that when a town is so situated that its sewage may be safely run off into a harbor or a river, so as not to become a nuisance afterward, this is the best method to pursue, as by a proper system of sewers

with house connections it offers less danger than any other system of producing infection. When such disposal is impossible without raising the sewage from reservoirs by pumps and discharging it into a river which at the same time has a tide that will carry much of the sewage back to the town, as is the case at London, the question of utilization presents itself. There are five principal systems of utilization: 1, irrigation; 2, filtration; 3, precipitation; 4, dry earth; 5, the pneumatic system. Irrigation has been the most largely practised, but it is contended by its opponents that deleterious organic compounds are taken up by the growing plants as well as scattered through the air in the process, and by exhalation from the soil. Its advocates insist not only that a large yield is secured, but that the crop is grown in as healthful a condition as by ordinary culture. It consists in distributing the sewage over the surface of the soil, from reservoirs into which the sewers empty or into which their contents are pumped. The objections are that infection is not sufficiently prevented, as before stated, and that, on account of topographical and geological conditions of the surrounding country, it is often impracticable. The advocates of filtration contend that it is economical and innocuous. Intermittent downward filtration is described as a variety of irrigation combined with deep drainage, so that the soil may be made to alternately receive the sewage and the air by which it is decomposed, freed of its poisonous qualities, and made fit to give nourishment to plants. Weare's process of filtration consists in filtering the sewage through charcoal, ashes, and soil contained in boxes, and is said to answer very well on a small scale. Precipitation is performed by several methods. The lime process of Gen. Scott, architect of the Albert hall, London, consists in mixing the sewage with a small proportion of milk of lime, agitating the mixture, and allowing it to subside. The precipitate is a very putrescible mud, and the liquid flows off in a tolerably clear condition, and has been used in the manufacture of a hydraulic mortar. But the precipitate contains only a small portion of valuable manurial constituents, and the drying of it is a very offensive operation. The superphosphate of lime (or Blythe's) process attempts to recover the ammonia from the sewage. Superphosphate of lime and a salt of magnesia are added under the supposition that an insoluble phosphate of magnesia and ammonia will be thrown down, but analyses show that a part of the phosphoric acid runs off in the solution. It was rejected by the English sewage commission. Holden's process mixes the sewage with sulphate of iron, lime, and coal dust. The "A, B, C" process, as it is called, or the process with albumen, blood, clay, and charcoal, has been worked by the "Native Guano Company," and is said to be successful. It consists in coagulating blood obtained from slaugh-

ter houses, together with whatever coagulable matters may be in the sewage, with sulphate of alumina, producing a flocculent precipitate which shall drag down by the aid of the heavy particles of clay the organic solids contained in the sewage; and the charcoal is for the purpose of absorbing gases. A company is working at Crossness, between Plumstead and the Erith marshes, at the southern outfall of the London drainage, which is there discharged at the rate of 50,000,000 gallons daily; of this 1 per cent. or 500,000 gallons is used by the company. A 15-horse-power steam engine throws the sewage into mixing tanks made of concrete, which are about 50 ft. long, 20 ft. wide, and 8 ft. deep. The details of the process, together with the sanitary and agricultural results, are given in the "Quarterly Journal of Science" for January, 1873. Disposal by dry pulverized earth in movable boxes has many advocates, who think that it could be advantageously applied to large towns; but it is the general belief that it is only adapted to those of considerably less than 100,000 inhabitants, requiring as it would the bringing in daily of dry earth to the amount of from 5 to 10 lbs. for each individual. The pneumatic system of disposal and utilization devised by Capt. Liernur has been applied at Amsterdam, Leyden, and other towns in Holland, where the disposal of excreta by water-carriage sewage is highly objectionable in consequence of the level of the canals being lower than that of the sea. It consists of the ordinary sewers for surface and house draining, and a second pipe system connected with an apparatus for manufacturing immediately and without loss the excreta into poudrette. The outlines of the process may be briefly stated as follows: The earthen hoppers of the houses are so constructed that the excreta fall to the lowest level of the soil pipe. Each hopper is covered with a rubber-seated lid, and is connected with a ventilator which passes up through the roof. At street corners, under ground, are large iron air-tight tanks, to a single opening in each of which all neighboring house pipes converge, this opening being closed with a gate. These tanks are connected in turn with large tanks at the great central sewage works of the cities. By means of air pumps a vacuum is created in the great tanks, and the gates of the pipes leading to the common receptacles being opened, the air is quickly removed from them and a vacuum created in each. The gates between them and their connecting house pipes being now opened, the matter within them is exhausted into the corner receivers, to be transferred to the great tanks at the central station, where it is manufactured into poudrette. This is accomplished by allowing the sewage to run into retorts perfectly fresh, all houses, tanks, pipes, &c., being emptied every few hours, mixing it with a small percentage of sulphuric acid to fix the free ammonia, and then running it into troughs in which revolve large

copper cylinders heated to a high degree, and the whole working in covered jackets. A thin layer of sewage is taken on at each turn of the cylinder, and by its heat is converted into dry poudrette, which is scraped off by a knife at the end of one revolution, and falls into a trough. No water is used in the house closets except the urine. The pipes being closed below and ventilated above, effluvia cannot escape into the houses, and there is no escape of sewer gas anywhere but at the central station under the furnace fires. The system, although embracing considerable outlay, is said to be not only self-supporting, but profitable, and to be extending over Europe.—See F. C. Krepps, "The Sewage Question" (London, 1867); Baldwin Latham, "Sanitary Engineering" (London, 1873); and Dr. Whitty, "On the Water Supply and Sewerage of Jerusalem."

SEWING MACHINE, a mechanical contrivance for uniting fabrics by means of needle and thread. The earliest inventions for this purpose were attempts to imitate hand sewing, making a running through-and-through stitch with but a needleful of thread. This being impracticable in consequence, among other defects, of the wearing of the thread, it was sought to produce the old crochet stitch by means of machinery. The first needle suitable for use in sewing machines was introduced by Charles F. Weisenthal, to whom a patent was granted in England June 24, 1755. It was pointed at both ends, with an eye in the middle, for passing each way through the cloth without being turned around; but it was only used for hand embroidery. The first application of machinery was contained in a patent to Robert Alsop in England, dated March 22, 1770, for embroidering in a loom with one, two, or more shuttles. Machine embroidery with a large number of needles was patented by John Duncan, May 30, 1804. He used hooked needles, attached in a straight line to a horizontal bar, the forward motion of which carried all the hooked ends through the cloth, when, on being supplied with thread by a feeding needle, the reverse motion carried back loops which passed through and secured those of the previous stitch. Patterns were worked by a sliding motion of the fabric with its vertical frame. This was the first important step in embroidering machinery, which was carried to great perfection in the machine of Heilmann. This however used Weisenthal's two-pointed needle with the eye in the middle, and also nippers to pull the needle through, afterward used by Greenough. There has lately been found in the archives of the English patent office a patent for a sewing machine made by Thomas Saint, dated July 17, 1790, which has excited considerable interest and surprise in consequence of its possessing many of the elements of successful modern sewing machines. This might have been used to some extent for sewing leather, but could not have succeeded with woven fabrics containing fibres,

for they would have been caught in the forked needle by which the thread was pushed through. It was intended, as the patent states, "for quilting, stitching, and making shoes and other articles by means of tools and other machines." It had an arm, upon the overhanging end of which there was a vertically reciprocating straight needle. The arm also supported a spool which gave out its thread continuously. It had a horizontal cloth plate, made a chain or crochet stitch, and had thread tighteners above and below. In fig. 1, representing this machine, *a* is the bed plate, *b* an upright post bearing a horizontal overhanging arm, upon the end of which are placed a needle *f* and an awl *g*, which were adjusted by means of set screws, and moved by cams *h* and *i*, on the shaft *k*. The needle was notched at its lower end, to push the thread through the hole made by the awl, and thus form a loop. The work was supported on a box *l*, sliding between guides *m, m*, and moved by a screw *n*

FIG. 1.—Saint's Sewing Machine, 1790.

turned by a toothed wheel *o*, which in turn was moved by an arm upon the shaft *k*. One loop was carried over the other by the bent point of the spindle *d* in a manner similar to that which has been employed in some chain-stitch machines. The screw *r* adjusted the box *l* on the guide plate. In 1830 B. Thimonier patented a sewing machine in France, 80 of which, made of wood, were in use in 1841 for sewing army clothing at a shop in Paris. They were destroyed by a mob, as the Jacquard loom and Hargreaves spinning jenny had been years before; but during the revolution of 1848 Thimonier was again at work with other machines capable of making 200 stitches a minute. The mob again broke up his establishment, threatened his life, and defeated his enterprise, and he died in poverty in 1857. Like that of Saint, his machine had a vertical needle descending from an overhanging arm, the fabric being fed upon a horizontal table by hand. The needle was driven

by a treadle instead of a crank as in Saint's machine, and was carried back by a spring. It had the form of a crochet hook, and being driven through the fabric caught a lower thread from a thread carrier and looper beneath, and brought a loop which it laid upon the upper surface, and at the next passage brought up another and passed it over the loop previously made, thus making a double loop or chain stitch, with the loops on the upper side. The Thimonier machine which was patented in France Aug. 5, 1848, and in the United States Sept. 3, 1850, was an improvement upon that of 1830, but retained its principal features, the needle being still worked by a treadle and spring. It is said that between 1832 and 1834 Walter Hunt of New York made a sewing machine in which he used an eye-pointed needle, attached to the end of a vibrating arm, which carried a thread through the fabric and made a loop which was pierced by a shuttle carrying another thread, making what is known as the lock stitch. When he applied for a patent in 1854 he was refused, because the main features which he claimed for his machine had been patented eight years previously by Elias Howe, and it was held that his right to a patent was forfeited by abandonment. A machine for making a through-and-through or shoemaker's stitch was patented Feb. 21, 1842, by J. J. Greenough of Washington. The needle was pointed at both ends, with the eye in the middle, and was drawn through one way and then the other by a pair of pincers travelling on a track and opening and closing automatically. It was designed for sewing leather and other hard material, and an awl pierced the hole in advance of the needle. The leather was held between clamps, which by means of a rack could be moved each way alternately to make a back stitch, or continuously forward to make the shoemaker's stitch. The needle was threaded with a length of thread, and required refilling. The rack, after passing forward its length, was each time set back. Another form of a through-and-through sewing machine employs fluted rollers, between which the cloth is drawn and crimped, and in this condition forced upon the needle and thence on the thread. In 1844 a patent was granted in England to Fisher and Gibbons for working ornamental designs by machinery, in which two threads were looped together, one passing through the fabric, the other looping with it on the surface without passing through. Curved needles were used beneath the fabric, and other needles with looped guides or retainers above, the several sets being arranged in a row across the machine. When the point of the curved needle ascended through the fabric, the point of the upper needle entered between it and its thread, and when the curved needle descended it left upon the upper needle a loop which was then pressed further on by the guide. The fabric was moved according to

the pattern required, when the curved needle again ascended and the upper needle passed its thread around it so as to be withdrawn through the loop previously on its stem. After this the upper needle, again advancing, entered between the curved needle and its thread as before, producing a highly ornamental double chain stitch.—Sewing machines may be divided into four classes, according to the character of the stitch they make: 1, those making the through, either continuous or back stitch; 2, those making the lock stitch; 3, those making a single-thread chain stitch, either the ordinary crochet stitch, or a twisted one called a twisted loop stitch; and 4, those making a double-thread loop or chain stitch. The through-and-through stitching machines, being no longer in use, will not be further described. The invention of the lock stitch has been claimed for Walter Hunt, but it has been generally conceded by sewing machine inventors that the machine of Elias Howe was independently devised; and as it had a more perfected construction and formed the basis upon which subsequent improvements were made, fitting it for a practically working machine, and obtained the first patent, he has been generally accredited as the originator of the lock-stitch machine. Howe's machine, as patented in 1846, used a grooved and curved eye-pointed needle, carried upon the end of a vibrating arm, which passing through the cloth formed a loop through which a shuttle passed another thread. The needle moved in a horizontal direction, the cloth being held in a vertical position by pins projecting from a baster plate, which was moved intermittently by a toothed wheel. On reaching the end of the plate, the machine was stopped, the baster plate returned to its original position, and the cloth again attached. This construction prevented the successful use of the machine. One of its serious wants was a device by which the cloth could be moved along in such a way as not to interfere with the functions of the needle, and this defect was then common to all sewing machines. Such a device is called the "feed," and was sought for a long time before the desired end was accomplished. One of the first steps was to make the needle vibrate vertically, and move the fabric along, or feed it on a horizontal plate, by the action of a notched wheel which rotated with its upper edge just passing through a slot in the horizontal plate. An intermittent motion was given to this wheel, which was sought to be so timed as to alternate with the passage of the needle through the cloth; but this arrangement was far from perfect, although it was for a time used with some success in the early machines made by Mr. I. M. Singer and others. It was not till the device known as the A. B. Wilson "four-motion feed" was introduced that this feature of the sewing machine approached perfection. This device consists in moving a serrated bar, in a slot in the horizontal plate upon

which the cloth is fed, in the direction of the four sides of a parallelogram. The teeth carry the cloth forward while moving horizontally a short space above the surface of the plate; the bar then drops (the second motion), then passes backward horizontally beneath the plate (the third motion), and rising brings the teeth through the slot and above the surface (the fourth motion). The directions of these motions are indicated in fig. 2. The motion which carries

Fig. 2.—Four-motion Feed.

the cloth forward is so timed by cams upon a wheel, or by eccentrics or other devices, as to take place while the needle is raised above the cloth, and never to interfere with its passage. The four motions are obtained in the Willcox and Gibbs machine by a single eccentric, and the number of stitches to the inch may be determined by a device which employs a dial with numbers upon it, showing through an opening in the cloth plate. Most of the sewing machines now in use are lock-stitch machines, the stitch being precisely the same in all, and the principle upon which it is formed being nearly the same also. It is always made by passing loops of thread through

Fig. 3.—Lock Stitch.

the fabric by means of an eye-pointed needle, and then passing another thread through these loops, this latter part of the process being usually produced by means of a shuttle which is made to pass through the loops. When the shuttle thread is pulled back half way through the fabric, the stitch has the construction shown in fig. 3, where the threads are raised from the cloth to give a better view. It will be seen that the position of either thread is the same in relation to either side of the cloth; but when the loops formed by the needle are not drawn into the body of the fabric, the shuttle thread will lie straight on the under side of the cloth, as shown in fig. 4. The manner of making

Fig. 4.—Lock Stitch.

the stitch with the shuttle is shown in fig. 5. In most machines the needle vibrates in a right line, being carried by a vertically moving needle bar which slides in grooves. A shuttle bar carrying a shuttle underneath the cloth plate is made to pass through the loop, which opens to receive it when the needle begins to retract. The two bars, the needle bar and the shuttle bar, being actuated by the same motor, are so adjusted that their times of motion exactly correspond to each other. The shuttle, passing backward with its bobbin

while the loop is drawn up into the cloth, only carries its thread through the loops in one direction, and unwinds just as much thread at each passage as corresponds to the curved

Fig. 5.—Shuttle.

length of the thread necessary to form a stitch. It is prevented from unwinding more than this by having the thread held by a device called a tension. The thread which is delivered by the needle is also held in the same way, in consequence of which the loop is retracted when the needle is drawn upward, the degree of retraction depending upon the tension, or the tightness with which the thread is held. The celebrated Singer and Howe machines are of this class, as also the well known Weed, Domestic, Florence, Remington, Wilson, American, Secor, and others. The Florence machine differs from the other lock-stitch machines in having a curved needle attached to the end of a vibrating arm, instead of being carried by a needle bar moving vertically in guides; and there are various ways of actuating the needle bars in all of them. Another form of lock-stitch machine, instead of causing a shuttle or movable bobbin to pass through the loop

Fig. 6.

Fig. 7.

formed by the needle, catches this loop by means of a rotary hook and passes it over a stationary bobbin, which answers to the movable shuttle, and may be regarded as a stationary shuttle. The lock stitch of the Wheeler and Wilson machine may be made by hand, and its formation explained by reference to fig. 6. Take a piece of fabric, *c*, an ordinary needle, *h*, threaded with *e*, and a small ball of thread, *f*; tie the ends of the two threads together, thrust the needle threaded head first through the fabric, and instead of passing the ball of thread through the loop *e*, hold the ball and pass the loop around it; withdraw the needle and draw the interlocked portion of the threads, *e* and *f*, into the fabric. A succession of stitches thus made will form a seam. The lock stitch is formed by the machine in an

analogous manner. The upper thread *e* is carried by an eye-pointed needle (35, fig. 7), and a loop of it is thrust through the fabric by the needle; the loop is then entered by the point *a* of the rotating hook. The lower thread *z* is carried upon a thin metallic bobbin lying in the concavity of the hook, where it is held by a concave ring (not shown). The bobbin has no axis, so that a loop of thread can be freely passed around it. The loop of the upper thread is enlarged by the hook (fig. 8), and carried forward and around the bobbin containing the

FIG. 8.

FIG. 9.

lower thread, as in fig. 9, and being drawn up as in fig. 8, in the process of enlarging the next loop, interlocks with it, and the point of interlocking is drawn into the fabric and forms a stitch. Wheeler and Wilson have made another form of lock-stitch machine, the invention of Mr. James A. House, which also employs a rotary hook, but completes a stitch at each revolution, drawing it up by a separate arm known as an independent "take-up." An eccentric attachment causes the hook to rotate more rapidly during one part of its revolution, and there is a "pad" or projection of steel on the revolving hook, or rather the wheel that carries it, by which the under thread is held firmly during a short period, which assists in the completion of the stitch. This produces the "tension," which can be regulated while the machine is in motion, and differs therefore from that just described in the family machine, which depends upon the friction of the revolving hook against the bobbin. The new machine is made of different sizes, some very large and strong, for heavy manufacturing work. The needle, being straight, is capable of penetrating stout leather. The medium sizes may also be used for tailoring as well as light domestic sewing.—The single-thread chain or crochet stitch is shown in fig. 10. It is formed by passing a thread through the fabric and making a loop, then making a second

FIG. 10.—Crochet Stitch.

loop and passing it through the first, and again making a third and passing it through the second, and so on. This may be done with

an eye-pointed needle and a reciprocating or vibrating hook, but does not form a very durable stitch, from its tendency to ravel. If, however, each loop is twisted, as shown in fig.

FIG. 11.—Twisted Loop Stitch.

11, ravelling is difficult, and when the work is well done not liable to occur, except by design. A mechanism for producing such a twist was patented by J. E. A. Gibbs of Millpoint, Va. A rotating hook causes the relations of the threads on each side to become changed toward each other. The different parts of the hook are shown in fig. 12, in which 18 is the shank, 19 the point of the hook, 20 the "cast-off," and 21 the heel; K K is the shield for protecting the thread from oil. In fig. 13 the needle, having descended to the lowest point, carrying down the thread, has just begun to ascend; and a loop is thrown off on the back

FIG. 12.

FIG. 13.

side of the needle just in time for the point of the hook to enter it. As the needle rises, the hook, moving in the direction of the arrow, passes into the loop, drawing it down and spreading it. As the hook advances from this point the loop begins to twist; thread No. 1,

FIG. 14.

FIG. 15.

fig. 14, moving to the right, slides off the shoulder at the centre of the hook and falls down to the shank, near the shield K, while the heel, 21, catches the back side of the loop 2, and swinging it around passes into the loop which is being reversed. As the hook still advances and the heel passes further into the loop, thread No. 2 slides into the angle at the centre of the hook, as seen in fig. 15. The loop is now completely reversed, thread No. 2 being on this side of the needle, and

thread No. 1 on the back side. While the old loop thus twisted and spread out is held open on the body of the hook, the point 19 enters the new loop and carries it into the old one, as seen in fig. 16; and as the hook continues to revolve the cast-off, 20, passes out of the old loop and leaves it to be drawn up to the under side of the fabric, as in fig. 17, which completes the stitch. One feature of the machine consists in the application of what is called an automatic tension, lately devised and patented by Mr. Charles H. Willcox. Instead of subjecting the thread to a continuous tension produced by partially confining it in a

FIG. 16.

FIG. 17.

groove or clamp through which the motion of the machine draws it, it is made to pass between two disks held together by a spiral spring firmly enough to hold the thread inflexibly and draw it through the fabric to a definite distance until more is required to make a new loop, when it is instantly relieved by a little piston rod striking against the lower end of a rod attached to the upper disk. A uniformity in the drawing up of each stitch is thus secured, and as the necessity for change in tension when different sizes of thread or thicknesses of cloth are used is done away with, no provision is made for change by the operator.—The Grover and Baker machine makes what is called the double-loop stitch, employing two threads. Instead of passing a single thread through the loop formed by the eye-pointed needle in piercing the cloth, as in

FIG. 18.

the lock-stitch machines, a loop made by a circular horizontally moving needle (fig. 18) below the cloth is passed through the former loop, and the needle at its next descent passes through the loop formed by the lower needle, so that the stitch is really formed by 'passing a loop of one of the threads through that of the other. The construction of the stitch thus made will be understood by inspecting fig. 19, where the threads are widely drawn apart for the purpose of showing it. When the loops are properly drawn to their places underneath the cloth, a durable elastic stitch is produced, which is very desirable in elastic as well as other goods, and may be used with advantage in embroidery by using different sized threads.—In this article it has been sought to explain the actions of some of the principal sewing machines, without entering into the details of their construction or a de-

scription of the various attachments for hemming, felling, ruffling, cording, &c., or of buttonhole machines, which are either attachments

FIG. 19.

to sewing machines, or made specially for this work, and which are employed with more or less perfection of execution.

SEXTANT (the sixth part), an instrument used in nautical observations and in hydrographic and land surveying for measuring the angular distance between objects. Its principle and the manipulation of it, in its ordinary form, are explained in the article **QUADRANT**, which instrument it has entirely superseded for observations at sea, partly on account of its greater portability, but mainly because of its capability of measuring a wider range of angles. For important land surveys a full circle is preferred, of which there are the following forms: 1. A simple reflecting circle, made by extending the arc of the sextant to a whole circumference and producing the index arm so that it can carry a vernier on each extremity. Observations with this are free from the error of eccentricity, and in part from the accidental errors of graduation and of reading, since they are derived from the mean of two readings at opposite divisions of the arc. 2. The repeating reflecting circle, which differs from the first only in having its horizon glass and telescope fixed to the arm which revolves about the centre of the instrument, instead of permanently attached to the frame. By taking a sufficient number of cross bearings with this, errors of reading, eccentricity, and imperfect graduation are essentially eliminated. In theory, therefore, the repeating circle is very nearly perfect, capable of eliminating its own errors. But as we cannot pretend to measure "what we cannot see," the refinement of the circle is really thrown away so long as an optical power is used so feeble as that of the telescope now employed; for in fact its results do not surpass those of the common sextant so much as was expected from its theoretical perfection. 3. The prismatic reflecting and repeating circles, which differ from the above only in substituting for the horizon glass a glass prism, which is fixed on the line of sight behind instead of in front of the index glass. The advantage of this arrangement is that angles of all magnitudes can then be measured. These are the transformations which the sextant has undergone to adapt it for the varied requirements of the practical astronomer and surveyor on land; but to satisfy the demands of the nautical astronomer and hydrographic surveyor, changes even more radical and varied

have been made. To the navigator the sextant is invaluable; and in the special work of hydrography along a coast line, where the position of the boat or vessel is generally determined by observing from the boat, the sextant is the only available instrument of precision in use. And yet in its ordinary form it has certain deficiencies which prevent its universality of application. This fails to measure the angles between 140° and 180° , and the hydrographers of all countries have studied to remedy this defect, with varied success. M. Daussey, a very skilful French hydrographer, and Messrs. Piston and Martius, instrument makers of Berlin, have in different ways modified the form of the sextant so as to overcome this difficulty; but their instruments are embarrassing in their manipulation, especially when the objects are indistinct or the observation must be made from a boat continually disturbed by the action of the waves. Mr. T. J. Lowry of the United States coast survey has succeeded in removing this imperfection in the sextant, and has also made other improvements by which many other difficulties are overcome. The improved instruments are handled with the same facility as the old sextant, and are equally adapted to rough usage in a boat. By means of some additional glasses and certain improvements in the graduated arcs and verniers, the following objects are accomplished: any angle from 0° to 180° can be measured without inverting the instrument and while reflecting but one object; two angles, one to the right and the other to the left of an object, either angle being any number of degrees from 0 to 120, can be measured at the same instant. By certain additions which are easily made to the ordinary sextant, Mr. Lowry makes the instrument capable of measuring two angles, one to the right and the other to the left of the central object, in quick succession, without previously estimating their relative magnitudes, or inverting the instrument or lengthening its arc. Lastly, by a modification of M. Daussey's improvement, Mr. Lowry makes the ordinary sextant capable of measuring an angle and giving an inter-range at the same instant, and also of fulfilling many other conditions which M. Daussey's will not.

SEXTUS EMPIRICUS, a Greek philosopher, a native of Mytilene, in the first half of the 3d century A. D. His medical writings are lost; but his *Pyrrhoniæ Hypotyposes*, in three books, an exposition of the doctrines of the skeptics, and a treatise against the mathematicians, in 11 books, in which he attacks all the sciences, both physical and metaphysical, remain. An edition of both, with a Latin translation, was prepared by J. A. Fabricius in 1718. Bekker published an amended edition (Berlin, 1842).

SEYCHELLES. See MAURITIUS, vol. xi., p. 293.

SEYDLITZ, or Seidlitz, Friedrich Wilhelm von, a Prussian soldier, born at Kalkar, near Cleves, Feb. 3, 1721, died near Namslau, Silesia, Nov.

7, 1773. He excelled in horsemanship from his boyhood. After serving as a page of the margrave of Schwedt, he entered the Prussian army in 1739, and won the rank of major at Hohenfriedberg, June 4, 1745, and that of major general at the battle of Kolin, June 18, 1757. In the same year he was put in command of the cavalry, and distinguished himself at Rossbach, Nov. 5, at Zorndorf and Hochkirch in 1758, and especially at Kunersdorf, Aug. 12, 1759, where he was seriously wounded, and at Freiberg, Saxony, Oct. 29, 1762. He was then made inspector of the cavalry in Silesia, and in 1767 general of cavalry, to which branch of arms he had imparted a wonderful efficiency.—See *Leben des Generals von Seydlitz*, by Varnhagen von Ense (Berlin, 1834), and *Der General Friedrich von Seydlitz*, by Count Friedrich Wilhelm von Bismark (1837).

SEYFFARTH, Gustav, a German archæologist, born at Uebigau, Saxony, July 13, 1796. He studied at Leipsic, where in 1825 he became extraordinary professor of archæology. In 1824 he published *De Sonis Litterarum Græcarum* (Leipsic). He edited and continued Spohn's *De Lingua et Litteris Veterum Ægyptiorum* (2 vols., 1825-'31), and published *Rudimenta Hieroglyphices* (1826). His *Grundsätze der Mythologie* (1843) and *Untersuchungen über das Geburtsjahr Christi* (1846) involved him in bitter controversies. His peculiar theory of hieroglyphics he maintained against Champollion, and he now (1875) claims that the Champollionists have passed off his system as their own. In 1855 he emigrated to the United States, and was for six years professor in the Lutheran seminary of St. Louis. In 1857 he published at New York a "Summary of recent Discoveries in Biblical Chronology, Universal History, and Egyptian Archæology," both in English and German, and in 1860 a pamphlet in German refuting the chiliasts. He has for some time been engaged on a work entitled "The actual Historical Chronology of the Romans, Greeks, Babylonians," &c. His last publication is "Clavis Ægyptiaca, a Collection of all Bilingual and some other Hieroglyphic Inscriptions, translated and explained."

SEYMOUR. I. Edward, duke of Somerset, an English statesman, known as the protector Somerset, born about 1500, beheaded on Tower hill, London, Jan. 22, 1552. He was the eldest son of Sir John Seymour, and was educated at Oxford. After the marriage of his sister, Jane Seymour, with Henry VIII., he was created Viscount Beauchamp and earl of Hertford, and gradually became one of the most powerful noblemen about the person of the king, his prestige being strengthened by military successes in Scotland and France in 1544. He was one of the 16 persons appointed by Henry VIII. in his will to be his executors and the governors of the young king, Edward VI.; and in February, 1547, he was created duke of Somerset and earl marshal of England. On March 12

he was appointed by patent protector and governor of the king and his realms. His brilliant victory over the Scots at Pinkie, Sept. 10, greatly strengthened his influence, and for upward of two years after the accession of his nephew his authority was invested with all the attributes of royalty. His leaning toward the commons and his attempts to reform various social evils aroused against him a powerful party, headed by the earl of Warwick, who had been one of his most confidential counsellors; while the zeal with which he had promoted the unjust condemnation and execution for high treason of his brother, Lord Thomas Seymour, disgusted the people. On Oct. 14, 1549, he was deprived of the protectorship and committed to the tower, whence he was released, with a full pardon, Feb. 16, 1550. He resumed his place in the council, but in October, 1551, was again arrested through the influence of Warwick; and being convicted of felony committed in an attempt to imprison the latter, he was executed. Somerset was sincere and consistent in his attempts to establish the doctrines of the reformation in England, and his government afforded protection to refugees, both political and religious. (See EDWARD VI.) **II. Lady Jane**, sister of the preceding, and third queen of Henry VIII., born about 1510, died Oct. 24, 1537. She was a maid of honor to Queen Anne Boleyn when the king first fell in love with her, was married to Henry on the day succeeding Anne's execution, and died 12 days after giving birth to Edward VI.

SEYMOUR, Horatio, an American statesman, born in Pompey, Onondaga co., N. Y., May 31, 1810. When he was nine years of age his parents removed to Utica. He was educated at the academies of Oxford and Geneva, N. Y., and Partridge's military school, Middletown, Conn., studied law, and was admitted to the bar in 1832. The death of his father devolved upon him the settlement of a large estate, and withdrew him from the practice of his profession. From 1833 to 1839 he served on the military staff of Gov. Marcy. In 1841 he was elected to the state assembly as a democrat, was reelected three times, and in 1845 was chosen speaker. In 1842, while in the assembly, he was elected mayor of Utica for one year. In 1848 he supported Lewis Cass for the presidency. In 1850 he was nominated by the democrats for governor, and was defeated by Washington Hunt, the whig candidate, by a plurality of 262 votes; but in 1852 he was elected governor by a plurality of 22,596 votes over the same competitor. A prohibitory liquor bill passed in March, 1854, was vetoed by him on the ground that it was unconstitutional. He was renominated in 1854. The prohibition question entered largely into the canvass, which was further complicated by the Know-Nothing issue and the anti-slavery agitation growing out of the repeal of the Missouri compromise. There were four candidates

for governor, and Myron H. Clark, whig and prohibitionist, was elected by a plurality of 309 votes over Gov. Seymour. In 1862 Mr. Seymour was again elected governor over Gen. James S. Wadsworth by a majority of 10,752 votes. In his inaugural address on Jan. 1, 1863, he said: "Under no circumstances can the division of the Union be conceded. We will put forth every exertion of power; we will use every policy of conciliation; we will guarantee them every right, every consideration demanded by the constitution and by that fraternal regard which must prevail in a common country; but we can never voluntarily consent to the breaking up of the union of these states or the destruction of the constitution." On June 15 Secretary Stanton, by direction of President Lincoln, telegraphed to Gov. Seymour asking if he could raise and forward 20,000 militia to assist in repelling the threatened invasion of Maryland and Pennsylvania by Lee's army; and within three days 12,000 soldiers were on their way from New York to Harrisburg. While these troops were absent from the state the draft was ordered to be enforced in the city of New York on July 11. On the 9th Gen. John E. Wool, commanding the department of the East, addressed a letter to Gov. Seymour setting forth that the city of New York was in a defenceless condition, and asked that he might be furnished with four companies of infantry. These companies were on their way thither from the interior of the state when Gen. Wool telegraphed, July 13: "Please countermand any militia that is ordered to this place." On the same day the draft riots began. The governor immediately went to New York, where on the 14th he issued two proclamations, one calling on the rioters to disperse, and the other declaring the city in a state of insurrection. He divided it into districts, which were placed under the control of military men who were directed to organize the citizens; and 3,000 stand of arms were issued to these and other organizations. Boats were chartered to convey policemen and soldiers to any point on the shores of the island where disturbances were threatened. The governor visited all the riotous districts in person, and by persuasion as well as by the use of the force at his command aided in quelling the disturbance. During his term Gov. Seymour commissioned more than 13,000 officers in the volunteer service of the United States. In 1864 he addressed a message to the legislature advocating the payment of the interest on the state bonds in gold; and the refusal of the legislature to adopt this policy greatly depreciated their value. In August he presided over the democratic national convention at Chicago, which nominated Gen. McClellan for the presidency. He also presided over the convention of 1868, held in New York. The leading candidates for the nomination were George H. Pendleton, Andrew Johnson, Thomas A. Hendricks, and Gen. W. S. Han-

cock. Gov. Seymour had positively declined to permit the use of his name as a candidate; but on the 22d ballot the Ohio delegation, to forestall a threatened movement in favor of Salmon P. Chase, cast their united vote for Horatio Seymour. When Wisconsin was reached in the call of states its delegation seconded his nomination, and every state changed its vote to Seymour, who was declared the unanimous choice of the convention. Gen. Francis P. Blair, jr., was nominated for vice president. At the election Seymour and Blair received 2,703,600 votes, against 3,013,188 votes for Grant and Colfax. Mr. Seymour lives on an extensive and well cultivated farm in Deerfield, near Utica. He is president (1875) of the national dairymen's association, and has delivered many addresses before agricultural societies. He is also president of the prison association of the United States.

SFORZA, an Italian family, several members of which were sovereign dukes of Milan during the 15th and 16th centuries. **I. Giacomuzzo Attendolo**, the son of a peasant and the founder of the house, born at Cotignola, in the Romagna, in 1369, died in 1424. He became one of the most redoubtable condottieri of Italy, and was surnamed Sforza on account of his muscular strength. He fought in the service of various princes, and Queen Joanna II. of Naples made him grand constable. In 1420, yielding to the influence of Pope Martin V., who had made him a count, he aided Louis III. of Anjou against the queen; but soon returning to Joanna, he protected her against Alfonso of Aragon, and while marching against Braccio di Montone was drowned in the Pescara. **II. Francesco**, duke of Milan, natural son of the preceding, born in 1401, died in 1466. He succeeded his father in the command of the mercenary bands upon whom his power rested. Enlisting in 1425 in the service of Filippo Maria Visconti, duke of Milan, then at war with a formidable league headed by the republic of Venice, he was defeated at Macalo by Carmagnola in 1427, but vanquished him in 1431 at Soncino. Under pretence of giving force to the decrees of the council of Basel against Eugenius IV., he wrested the province of Ancona from the pope. Entering the service of the Florentine republic against Visconti, he beat the Milanese under Piccinino and conquered Lunegiana in 1437; returning to his former ally, was sent by him to Naples to support René of Anjou against Alfonso of Aragon; then going over again to the Venetians, defeated Visconti in 1440, and invaded his territory; and finally, receiving the hand of the duke's illegitimate daughter Bianca, forced Florence and Venice to grant that prince the peace of Capriana (1441). Visconti treacherously attempted to crush his son-in-law by forming a league of nearly all the Italian princes against him; but, concentrating his whole force in the province of Ancona, Sforza routed his enemies at Monte Lauro and Mont' Olmo in 1444;

and when, notwithstanding these successes, he was on the eve of succumbing to superior forces, he received timely aid from the republic of Venice and from Florence, now under the control of his friend Cosmo de' Medici. On the death of Visconti without a male heir in 1447, the Milanese adopted a republican government; but Sforza, after serving the republic for a time, seized its principal towns, blockaded Milan, and in 1450 was proclaimed duke. Venice and Naples refused to acknowledge his title; but he defeated the former in a short war, made peace and contracted an alliance with Alfonso of Aragon, king of Naples, made himself master of Genoa in 1464, and secured a controlling influence in all Italy. His protection of science and literature, his liberality toward the learned exiles from Constantinople, and the public improvements accomplished under his reign, entitle him to a high rank among the princes of his age. **III. Galeazzo Maria**, son and successor of the preceding, born in 1444, assassinated in 1476. He was serving Louis XI. of France at the time of his father's death, and returned hastily in disguise to Milan, where, owing to his mother's energy, he was proclaimed duke; but he gave himself up to luxury and debauchery, and was charged with poisoning his first wife and his mother. His second wife was Bona of Savoy, sister-in-law of Louis XI. He was assassinated by three conspirators, and Giovanni Galeazzo, about eight years old, was proclaimed duke under the regency of his mother. **IV. Ludovico**, called *Il Moro*, brother of the preceding, born in August, 1451, died in 1508 or 1510. In 1479 he assumed the title of regent in Milan. His nephew, a son-in-law of Ferdinand, king of Naples, being treated as a prisoner, Ferdinand was arming against Ludovico, when the latter in 1494 invited Charles VIII. of France to undertake the conquest of Naples; and Galeazzo dying soon after, Ludovico proclaimed himself duke. He now formed a league of all the northern powers of Italy to prevent Charles's return from Naples; but the French baffled his efforts, and in 1499 he was attacked by Louis XII., who claimed the duchy in the right of his grandmother Valentina Visconti, and being forced to fly from Milan took refuge at Innspruck, with the emperor Maximilian. The French gave such dissatisfaction to the Milanese that, with the aid of mercenary Swiss troops, Ludovico was enabled to reconquer his duchy; but on a new invasion of the French in 1500, he was taken while trying to escape, and confined for life in the castle of Loches. **V. Massimiliano**, son of the preceding, born in 1491, died in June, 1530. He was made duke by the "holy league" in 1512, after the expulsion of the French, but was overthrown on their return in 1513. On the defeat of the French army at Novara he reëntered Milan, but finally lost his crown in 1515, when Francis I. of France won the victory of Marignano (Me-

legnano), and gave up all his rights to it on condition of receiving a pension, and went to France. **VI. Francesco II.**, younger brother of the preceding, born in 1492, died Oct. 24, 1535. In 1522 he received the duchy in fief from the emperor Charles V., but made himself odious by imposing onerous taxes. He left no issue, and the duchy reverted to Charles V.

'SGRAVESANDE. See GRAVESANDE.

SHACKLEFORD, an unorganized N. W. county of Texas, intersected by the Clear fork of the Brazos river; area, 900 sq. m.; pop. in 1870, 425, of whom 55 were colored. Stock raising is the chief occupation.

SHAD, a well known fish of the herring family, of the genus *alosa* (Cuv.), differing from the herrings proper (*clupea*) in having the centre of the upper jaw deeply notched. The lower jaw is the longer; the teeth are small and deciduous, in the jaws only; the air bladder is simple, opening from the stomach. The genus comprises more than 20 species, among which are the alewife, blue-back, menhaden, and shad herring. The American shad (*A. præstabilis*, De Kay, or *A. sapidissima*, Storer) attains a length of about 20 in., and varies in weight from 2 to 6 lbs.; the upper parts of the

American Shad (*Alosa præstabilis*).

sides and gill covers are coppery, lower part of sides silvery, abdomen pearly, and top of head and back bluish; a more or less distinct black blotch at the posterior angle of the gill cover; irides silvery; dorsal on anterior part of back, quadrangular, transparent, and shutting in a groove; pectorals and ventrals small, and anal low and partly received in a groove; caudal deeply forked, with a patch of small scales and two membranous appendages at its base; scales large, and abdominal ridge serrated. They come from the south to deposit their spawn, running up the rivers from the sea; they appear at Charleston in January, at Norfolk in February, at New York by the end of March or beginning of April, at Boston by the end of April, and in the bay of Fundy by the middle of May. They appear in the Massachusetts rivers early in May, the greatest run being when the apple trees are in full blossom; the shad fly (*hemerobius*) appears at the same time, covering the houses and fences; the old return to the sea in August, and the young, 3 or 4 in. long, migrate in September. It is a common belief that the life of the shad is limited to a single year. The Massachusetts fish commissioners in 1874 hatched great numbers of shad in the Merrimack river at North Andover. The

number caught there in that year was 1,680, which furnished 6,249,000 spawn; of these 3,500,000 were hatched and distributed in various waters of the state. The average of the yield of eggs was 10,278 to each female. For other efforts toward the propagation of shad, see FISH CULTURE, vol. vii., pp. 219 and 222. In the Delaware and Hudson rivers, whence New York is mainly supplied, the shad fishery is prosecuted by drift and stake nets, and its commercial value is considerable. The fish are with us mostly eaten fresh, and are delicious, the only drawback being the innumerable bones; they lose their flavor the longer they remain in fresh water. They will rise to a gaudy fly in fresh water, and afford very exciting sport. Their food in salt water consists principally of worms like the shad or slug worm, and shrimps. The shad fishery is of considerable importance to the British provinces; in the upper part of the bay of Fundy, on the New Brunswick side, the fishing is mostly carried on in the channel by drift nets from 25 to 30 fathoms long, sinking to a depth of about 16 ft., with meshes of $4\frac{1}{2}$ to 5 in.; it continues from July to the middle of September; the fish are split and salted, and mostly used in the neighborhood. Shad are sometimes caught in standing weirs set on the flats, but these soon destroy the fishery, as fish of all sizes are taken; in standing nets many fine fish are lost by falling out unless narrowly watched. Stake nets are each about 100 fathoms long, set on stakes or poles about 15 ft. apart on the mud flats, and are dry at low water; most of the fish in these are caught on the ebb tide. This fishery is also of importance on the Nova Scotia side of the bay of Fundy; shad are also taken in the gulf of St. Lawrence.—The hickory shad (*A. lineata*, Storer) is about 15 in. long, silvery on the sides, with six or eight indistinct bluish longitudinal bands; it is lean, and is not used for food.—The European shad (*A. vulgaris*, Val.) ascends the Thames and the Severn, the Elbe, Rhine, Seine, Loire, Garonne, Volga, and other rivers, from the Atlantic and other seas, in numerous troops during the spring, varying greatly from year to year. It attains a length of 2 to 3 ft., and is dark green above and silvery below, with a dusky patch behind the gill covers; its flesh is little esteemed in England. Cuvier and Yarrell describe the *A. finta*, the twaite shad or May fish, about 14 in. long, with teeth in both jaws and several black spots on the sides, and a dry insipid flesh. Valenciennes maintains that this is only the young of the *A. vulgaris* before the teeth have fallen, and declares that only one species is found in the waters of Europe.—The head of the shad presents a good example of the water tubes through which, in many fishes, fluid is introduced into the blood and the system generally; the object of this apparatus, often very extensive, is commonly said to be for accommodating the body to the pressure of different ocean depths.

SHAD BUSH. See JUNE BERRY.

SHADDOCK, a fruit of the *citrus* or orange genus, noted for its great size. In treating of other members of this genus the difficulty of tracing the commercial varieties to botanical species has been alluded to, and the same doubt surrounds the shaddock. The fruit was brought from Asia to the West Indies by an Englishman, Capt. Shaddock. De Candolle is disposed to regard it as a species, not on account of the size of the fruit, but because the leaves are downy on the under side and ciliate on the margins. The shaddock is a native of China and Cochin China, but is thoroughly established in the West Indies, where it presents many varieties. The tree and fruit are

Shaddock (*Citrus decumana*).

much larger than those of the common orange, but it can hardly be regarded as a valuable fruit, as its quality is very inferior. Its specific name, *decumana* (Lat., immense), refers to its size, the fruit of shaddock often weighing 6 or 8 lbs.; it is mainly useful in making up ornamental collections of tropical fruits.

SHADWELL, Thomas, an English dramatist, born in Norfolk in 1640, died in 1692. He was educated at Cambridge, settled in London, and wrote for the stage. He obtained so great a reputation as a writer that he was set up as a rival of Dryden, on whose dismissal in 1688 he became poet laureate. He is now chiefly known as the hero of Dryden's satire of "MacFlecknoe;" but the dulness there ascribed to him is altogether imaginary. His

works were published collectively in 1720 (4 vols. 12mo).

SHAFTESBURY. **L. Anthony Ashley Cooper**, first earl of, an English statesman, born at Wimborne St. Giles, Dorsetshire, July 22, 1621, died in Amsterdam, Jan. 22, 1683. His father was Sir John Cooper, of Rockbourne, Hants, and his mother Anne, daughter of Sir Anthony Ashley, Queen Elizabeth's secretary of war. He studied at Exeter college, Oxford, and at Lincoln's Inn, and represented Tewkesbury in the short parliament of 1640. In the civil war he first supported Charles I., but in 1644 went over to the parliament, raised a force in Dorsetshire, stormed Wareham, and reduced the surrounding country. He was a member of Cromwell's parliaments, and was appointed by the Barebones parliament one of the council of state, though openly opposed to many of Cromwell's measures. He retired from the council in 1654, and was a leader of the opposition in parliament both before and after Cromwell's death. He was active in the overthrow of the second protectorate and the restoration of Charles II., being a member of the commission sent to Breda to invite his return, and was appointed governor of the isle of Wight, lord lieutenant of Dorsetshire, chancellor of the exchequer, and a privy councillor, and in April, 1661, was created Baron Ashley. He was one of the commission for the trial of the regicides, whom he prosecuted with zeal. In 1667 he was made joint commissioner of the treasury. His title furnished the second letter for the name Cabal given to the Clifford ministry (see CABAL), and he has been charged with the scheme of shutting up the exchequer. In 1672 he was created earl of Shaftesbury and made lord chancellor. He had no legal knowledge, was ignorant of his duties, and servile to the king. Suddenly he began to oppose the government of which he was a member, and the king dismissed him (1673). His opposition now became very violent, and in 1677 he was committed to the tower, where he remained more than a year, and was not released until he begged pardon on his knees. Oates's "popish plot" made him powerful, and he was the author of the test bill of 1678, under which Catholics were excluded from parliament during 151 years. As president of the new permanent council he became nominal chief of the government; but, aware of the instability of his condition, he determined that the duke of York should be excluded from the succession. In 1679 he framed and caused to be passed the *habeas corpus* act. Parliament being dissolved and Shaftesbury dismissed, he became more violent than ever, induced Monmouth to return home, and tried to procure the indictment of the duke of York as a recusant. In the parliament of 1679 the commons were completely under his influence, and he carried resolutions against the duke of York, and caused the exclusion bill to be again brought forward, which rapidly passed

the lower house, but was thrown out by the lords. The king again dissolved parliament, and the next one met at Oxford; but Shaftesbury being still all-powerful in the commons, it was soon dissolved (1681). The earl was arrested by order of council on the charge of high treason, and the benefit of his own *habeas corpus* act was denied him; but the grand jury threw out the bill, and the earl was liberated. He left England, and reached Amsterdam in 1682, where he was admitted to the magistracy. This secured his personal safety, and for the remainder of his life he lived in splendor. He wrote memoirs of his own times, and intrusted them to his friend John Locke, who destroyed them, frightened, it is said, by the execution of Algernon Sidney. His life was written and privately printed under the direction of his great-grandson (new ed., 1836). See also "Life of the first Lord Shaftesbury," by W. D. Christie (London, 1871). **II. Anthony Ashley Cooper**, third earl of, grandson of the preceding, born in London, Feb. 26, 1671, died in Naples, Feb. 15, 1713. He entered parliament in 1693, and made a famous speech in behalf of the proposal to allow counsel to persons charged with high treason. Illness compelled him to retire from public life in 1698. He entered the house of lords in 1700, supported the measures of William III., and on the king's death retired. He was a philanthropist and a leading free thinker, and wrote "A Letter on Enthusiasm" (1708); "Moralists" and *Sensus Communis* (1709); and "A Soliloquy, or Advice to Authors" (1710). A complete collection of his works was published under the title "Characteristics of Men, Manners, Opinions, and Times" (3 vols. 8vo, 1713). At the time of his death he was engaged in Naples upon a work on the arts of design. **III. Anthony Ashley Cooper**, seventh earl of, born April 28, 1801. He graduated at Christ Church college, Oxford, in 1822, was returned to parliament in 1826, and supported the administration of George Canning. He was repeatedly a member of the house of commons, and entered the house of lords in 1851. He has continually striven to improve the condition of the laboring classes, and has taken part in many religious and benevolent enterprises.

SHAG. See CORMORANT.

SHAGREEN (Pers. *sagri*, *shagrain*), a preparation of the skins of horses, wild asses, and camels, resembling parchment more than leather. It is a product of Astrakhan in Russia and the countries of the East. Thick strips are cut from the skins along the chine, and having been deprived of the hair and dressed in the usual process of currying, each one is stretched by strings fastened to its edges in a square wooden frame. It is kept moist, and is occasionally stretched still more, till it becomes smooth and tense as a drum head. While still moist, the hair side is sprinkled over with the hard shining black seeds of a species of *cheno-*

podium, and these being covered with a piece of felt or thick cloth, the seeds are pressed into the skin by trampling or by a simple press. The skin retaining the seeds is then dried in the shade, and being afterward beaten the seeds fall out, leaving the surface indented with their pits. The opposite smooth side is then shaved down nearly to the bottom of the pits, and on macerating the skin in water the depressions appear in little swellings on this side, which become hard with the rest of the skin when dried. The strips being steeped in a warm solution of soda, and cleansed with salt brine, they are ready for dyeing. Shagreen was formerly much used for sword scabbards, instrument and spectacle cases, &c.

SHARP, John Campbell. See supplement.

SHAKERS, the popular name of a religious sect who call themselves the "United Society of Believers in Christ's Second Appearing." They originated in England about the year 1770, but are now confined to the United States, where they have 17 societies and about 4,000 full members, besides some hundreds of novitiates. They were at first an offshoot from the Friends or Quakers, and generally held similar views relative to spiritual illumination, giving testimonies, objecting to the legal oath, to war, slavery, &c.; but in their theological ideas, as well as in their practice of celibate life, and in community of goods, they now differ entirely from the Friends. In 1747 some members of the society of Friends near Manchester, England, formed a distinct association, of which Jane and James Wardley were the leaders. Of this society the parents of Ann Lee were members, and in 1758 she became one of its adherents. For several years this little company were only remarkable for greater physical manifestations of their spiritual illumination than most of the assemblages of Quakers, such as dancing, shouting, trembling, speaking with tongues, &c. These manifestations excited the hostility of the populace, and even of some magistrates and clergymen, who charged them with thereby violating the sabbath. Several of the members, including the Wardleys and Ann Lee and her family, were imprisoned, fined, and roughly used. In 1770 Ann Lee professed to have received, by a special manifestation of divine light, those revelations in virtue of which her followers have ever since given her the name of Mother Ann, and have regarded her as a person inspired by the Christ of the female order, as Jesus was inspired by the Christ of the male order. Christ is applied by them, as a generic term, to the highest or innermost sphere, exterior to the deific sphere, called in the Scriptures eternity: "the high and lofty One that inhabiteth eternity." In 1774, under authority of a revelation to Mother Ann, ten of the more prominent members of the society, including Ann Lee, emigrated to America, arriving in New York Aug. 6; and eight of them subsequently settled at Niskayuna (now Watervliet), 7 m.

from Albany. Here they remained, without any considerable accession to their numbers, for 3½ years. In 1779 a religious excitement, or revival, occurred at New Lebanon, Columbia co., N. Y., accompanied by those extraordinary physical manifestations which subsequently characterized a similar revival in Kentucky. When these manifestations had subsided, in the spring of 1780, some of those who had been most affected by them visited Mother Ann at Watervliet, and there, as they believed, found the key to their religious experiences. The number of adherents to her doctrines increased rapidly up to the time of her death in 1784, and indeed for some years after.—The idea of a community of property, and of Shaker families or unitary households, was first broached by Mother Ann, who formed her little family into a model after which the general organizations of the Shaker order as they now exist have been arranged. In 1787 Joseph Meacham, formerly a Baptist preacher, who had been one of Mother Ann's first converts at Watervliet, collected her adherents in a settlement at New Lebanon, and organized them in this form, probably adding some principles not found in Mother Ann's revelations. Within five years, under the administration of Meacham, 11 Shaker settlements were founded, viz.: at New Lebanon, N. Y., which has always been regarded as the parent society; at Watervliet, N. Y.; at Hancock, Tyringham, Harvard, and Shirley, Mass.; at Enfield, Conn.; at Canterbury and Enfield, N. H.; and at Alfred and New Gloucester, Me. No other societies were formed till 1805, when three missionaries from New Lebanon visited Ohio and Kentucky, and were ultimately successful in founding four societies in Ohio (Union Village, Watervliet, White Water, and North Union), and two in Kentucky (Pleasant Hill and South Union). These settlements are composed of from two to eight "families," or households. A large house, divided through the middle by wide halls, and capable of accommodating from 30 to 150 inmates, is erected for each family, the male members occupying one end and the females the other. The property is owned by each family as a community. The societies all possess considerable tracts of land, averaging nearly seven acres to each member. They believe idleness to be sinful, and every member who is able to work is employed. They have usually very extensive gardens connected with their settlements, and the culture of flowers, medicinal herbs, fruits, and vegetables has been a favorite business with them; and they have dealt largely in garden and flower seeds, dried herbs, and medicinal extracts. Of late years they give more attention to agriculture and to manufacturing than formerly. The broom business is extensively carried on by all the societies. They usually have at their villages storehouses and separate buildings for dairy or mechanical purposes, a school house for the children they adopt or who come in with their

parents, and a meeting house or hall. Their schools are supplied abundantly with apparatus and libraries.—In their mode of worship they exercise both soul and body. The two sexes are frequently arranged in ranks opposite to and facing each other, the front ranks about 6 ft. apart. There is usually an address by one of the elders upon some doctrinal subject, or some practical virtue, after which they sing a hymn; then they form in circles around a band of singers, to whose music they "go forth in the dances of them that make merry." At times the excitement and fervency of spirit become very great, and their bodily evolutions, while maintaining the order and regularity of the dance and the music, are almost inconceivably rapid. They believe themselves to be frequently under the immediate influence of spirit agency, both of angels and of departed members of their own fraternity, who have advanced further in the work of the resurrection or redemption from the generative nature and order than those still in the body. They have a ministry, composed of two brethren and two sisters, who have the oversight of from one to four societies; also each family in every society has four elders, two brethren and two sisters, who have charge of the family. The temporalities of each family are cared for by two deacons and two deaconesses. There are three classes of members: 1. The novitiates, who, receiving the doctrines of the Shakers, and living up to the general requirements of their faith, still prefer to reside with their own families, and manage their own temporal concerns, for a time. They are not controlled by the society, either as to their property, families, or children, and enjoy their spiritual privileges in connection with it, unless they violate its rules and principles. 2. The junior class, composed of persons who have become members of the Shaker communities, and unite in their labors and religious exercises, but who have not relinquished their property to the society, or, if they have given the society the improvement of it, may at any time resume it, though without interest. 3. The senior class, comprising those who, after full experience of the system of the Shakers, voluntarily and deliberately consecrate themselves, their services, and all their property to the society, never to be reclaimed by them or their legal heirs. Those belonging to this class are called the church or senior order. No difference is ever made in this order on account of the amount of property any individual may have contributed. They, as well as all who retain their connection with the community, are amply provided for, in health, sickness, and old age.—The Shakers hold that the revelation of God is progressive; that in the first or antediluvian period of human history, God was known only as a Great Spirit; that in the second or Jewish period, he was revealed as the Jehovah, He, She, or a dual being, male and female, the "I am that I am;" that Jesus,

in the third cycle, made God known as a Father; and that in the last cycle, commencing with 1770, "God is revealed in the character of Mother, an eternal Mother, the bearing Spirit of all the creation of God." This last they regard as a revelation of God's affectional nature, as a manifestation of the divine love and tenderness. The Christs they believe to be also dual, male and female, supramundane beings. Jesus, in their system, was a divinely instructed, pure, and perfect man, and by virtue of his anointing became Jesus Christ. Among the doctrines of the new revelation are the immortality of the soul, which Moses never taught, and the resurrection of the soul, by which they understand the quickening of the germ of a new and spiritual life, after the death of the first Adamic or generative life. All who marry and are given in marriage, or who indulge in the earthly procreative relation, they term "the children of this world," and followers of the first Adam. They do not condemn them for living in the marriage relation, provided they confine its use simply to the purpose of procreation, the production of offspring being the only justification of sexual intercourse; all beyond that they designate as "the unfruitful works of darkness," and they sincerely condemn it as mere sensual gratification. But Shakers, as Christians, hold that they are called to lead a spiritual and holy life, not only free from all lust and carnal sexual indulgence, but even to rise above the order of natural and innocent human reproduction (proper enough for the "children of this world," and in a measure for gentle Christians), Shakers being the "children of the resurrection," daily dying to the generative nature, as Jesus and the apostles died to it, and thus becoming new creatures who are able to comprehend the "mysteries of God." Another doctrine, in which they believe "Christ instructed Jesus," is human brotherhood, and its development in a community of goods, according to the example of Jesus and his apostles. The doctrines of non-resistance, non-participation in any earthly government, and the necessity of a life of celibacy and virgin purity to a perfect Christianity, they regard as having been communicated to Jesus by a Christ Spirit; and, though neglected by the church in the past, of prime obligation to the true believer. The second appearing of the Christ, "without sin unto salvation," they believe to have taken place, through Mother Ann Lee, in 1770. She, "by strictly obeying the light revealed in her, became righteous even as Jesus was righteous. She acknowledged Jesus Christ as her Head and Lord, and formed the same character as a spiritual woman that he did as a spiritual man." The necessity for the appearing of Christ in the female form resulted from the dual nature of Christ and of Deity. "Still it was not Jesus nor Ann, but the principles already stated, which were the foundation of the second Christian church. Their importance is derived from the fact of

their being the first man and the first woman perfectly identified with the principles and spirit of Christ." This second appearing of Christ they hold to be the true resurrection state, and repudiate a physical resurrection as repugnant to science, reason, and Scripture. As they recognize four dispensations or cycles of human religious progress, so they believe there are heavens and hells to each cycle, which are still places of probation. The first dispensation, and its heaven and hell, were respectively for the good and wicked among the antediluvians, and the wicked of that cycle were "the spirits in prison" to whom Jesus preached in the interval between his death and ascension. The second dispensation (by Moses) was designed to teach by revelation God's truth pertaining to the earth-life chiefly. The second hell they name Gehenna, and consign to it the Jews and heathen who died before the coming of Jesus; the second heaven is paradise, where the thief on the cross had the promise of going after his death. They believe that a perfect system of agriculture, horticulture, and hygiene was gradually unfolded in the statutes of Moses, obedience to which, then and now, would give entire exemption from physical disease or bodily infirmity; and that the principles contained in those laws and statutes are to-day as binding upon all Christians as are the ten commandments. (The Shakers eat no pork.) All human sickness, they say, is the result of some physiological sin, direct or indirect, against the teachings of Moses. In proof of this position they cite the promise of Moses to Israel: in obedience, "the Lord thy God shall take all sickness away from the midst of thee;" but in disobedience, he will "bring back upon thee all the diseases of the Egyptians," of which they were afraid, and of which diseases Moses had cured them in the wilderness, by means of the physiological treatment under which he put at least 2,000,000 persons, giving them for food simple manna, for drink and bathing cold water, and to breathe the pure air in open well ventilated tents. The third dispensation is that of the church of the first appearing of Christ, and to its heaven Paul was caught up. The fourth heaven is now forming; in it Jesus and Mother Ann reside, and to it will all those go who have resisted temptation until all their evil propensities and lusts are destroyed, and the life of the generative natural man is dead in them, for such are born of God and cannot sin. No one but Jesus had ever attained to this previous to the second appearing of Christ in Ann Lee. It is the heaven of heavens, and to it will be gathered not only all who accept the doctrines of the Shakers in this world, and attain to the new birth, but all those in the lower heavens and hells who shall yet accept them; and when their decision is finally made, the lower heavens and hells and the earth will be destroyed, and only the fourth heaven for the true believers, and the fourth hell for the finally impenitent,

will remain. Each cycle has had its own Holy Spirit, the spiritual influx from the church in the heaven of that cycle to the inhabitants of earth at the time. They hold to oral confession of sins to God, in the presence of one or two witnesses, as essential to the reception of the power to forsake sin. They also believe in the power of some of their members to heal physical diseases, by means of prayer and dietetics. The Bibles of different races they consider as records of the most divine angelic ministrations to man (for they hold that the natural man never has seen and never will see God), and as more or less imperfect records of the religious experience and history of the Jews and other peoples. They believe that the mental and spiritual condition of those seers and prophets, whose prophecies form a considerable part of all Bibles, has materially modified the revelation, and that it has been further modified and impaired by the translators of the Scriptures; the book of Revelation has suffered less in this respect than any other, mainly because it is utterly unintelligible to the generative man, and could not be comprehended till the second appearing of Christ, as that was the only key to unlock its mysteries. The revelations of Ann Lee, and others of their ministers and elders who have been inspired by God to speak, they regard as valid and important.—The movement of the spiritualists has excited great hopes in their minds of a remarkable influx of disciples to Shakerism, inasmuch as they consider it a preparation of the people to receive their doctrines. Their increase during the present century has been moderate, only three societies having been formed within the past 60 years, and the growth of those previously in existence having been slow; but it is worthy of note that they are the only people on this continent, if not in the world, who have maintained successfully for nearly a century a system of living, one of the fundamental principles of which is a community of property. The Shakers are spiritualists in a practical sense. They hold Swedenborg as the angel of spiritualism mentioned in the 18th chapter of Revelation. He is their John Baptist. Spiritualism had very much subsided in the order until 1837, when a renewal of it occurred, lasting seven years. This was the commencement of modern spiritualism, four years before the Hydeville rappings. The spirits predicted that after performing a certain work in the world, they would return to the Shakers, and replenish their numbers from the ranks of the spiritualists. According to Elder Frederick W. Evans, this return of the spirits is now occurring in the form of world-troubling materialization. He visits the most trustworthy of the mediums, and invites them to Mount Lebanon to have their powers tested.—The Shakers have published since 1870 the "Shaker and Shakeress," a monthly, edited by F. W. Evans and Antoinette Doolittle, at Mount Lebanon, Columbia co., N. Y.

SHAKESPEARE, William, an English dramatist, born in Stratford-upon-Avon, Warwickshire, in April, 1564, died there, April 23, 1616. The exact date of his birth is not known; but as there is a tradition that he died on its anniversary, and as the parish record of Stratford shows that he was baptized April 26, 1564, and it was common at that period to baptize children on the third day after their birth, the 23d of that month has, with much probability, been assumed as the day of his birth. His father was John Shakespeare, probably the son of Richard Shakespeare, a well-to-do farmer of Snitterfield, 3 m. from Stratford. Traces have been discovered of the family's existence in various parts of that country as early as the 14th century. John Shakespeare was a substantial yeoman, who is called, in parish record and tradition, successively a glover, a yeoman, a gentleman and freeholder, a butcher, and a wool stapler or wholesale dealer in wool. He seems to have been a man of intelligence and character; for he passed through the offices of ale-taster, burgess, constable, affeerror, chamberlain, alderman, and high bailiff, to that of chief alderman and *ex officio* justice of the peace. Like many others of even higher rank than his at that time, he could not write his own name. He married Mary Arden, the youngest daughter of Robert Arden of Wilmecote, a hamlet partly in the parish of Stratford. The Ardens were of the acknowledged gentry of Warwickshire; their family was ancient, and of some note in the county. Robert Arden was a considerable landed proprietor, although his daughter Mary inherited from him only an estate of about 54 acres, called Ashbies, at Wilmecote, and a small interest in some other land and tenements near by, with £6 13s. 4d. in money, which was equal to about £40 at this time. The marriage took place in the latter part of 1557. William Shakespeare was the third child and the first son of a family of eight. He had three brothers, none of whom attained any distinction. In his infancy and early youth his father's circumstances were easy. He owned two houses, each having a garden and one a croft attached to it; he rented a small farm, and bought at least two more houses with gardens and orchards. The house in Henley street, Stratford, in which it may safely be assumed that he lived from his marriage, if not five years before it, until his death, was a pretty and commodious dwelling. It was divided into two, and allowed to go to ruin in the latter half of the 17th century. There was an endowed grammar school at Stratford, among the pupils at which we may safely assume, having the support of tradition, was the son of the high bailiff and chief alderman of the town. What amount of learning Shakespeare acquired before he entered active life has been much disputed. Certain critics, the most prominent of whom are Charles Gildon and John Upton, have asserted for him a very considerable

scholarship; others, at the head of whom is Dr. Richard Farmer, with much ingenuity and some reason, argue that he was ignorant of any language but that of which he was the greatest master. But his friend Ben Jonson, himself a very thorough and laborious, if not a very profound or variously learned scholar, said that Shakespeare had "small Latin and less Greek;" from which statement we may reasonably infer that he knew enough of the former language to master such passages of it as he encountered in the course of discursive reading (and in his day these were many), though not enough to read Latin authors for pleasure, and that he had the benefit of some instruction in the latter tongue. His notably frequent use of Latin derivatives in their radical sense favors this view. Of Italian and French he seems to have acquired some knowledge in his youth or early manhood. Shortly previous to 1578 John Shakespeare's affairs became much embarrassed. In that year he mortgaged his property; his assessments by the corporation were reduced to one third of those paid by other aldermen; he was next excused from paying anything for the relief of the poor; and finally an execution against him was returned "No effects," and another Stratford burgess was elected in his place, because he had long neglected to attend the "halls" or corporation meetings. He also, because he feared process for debt, which could then be executed on Sunday, remained away from church, and thus incurred suspicion of nonconformity. He however contrived to retain possession of his house in Henley street. Thus straitened in his means of livelihood, John Shakespeare would naturally seek to make his eldest son contribute something to the support of the family; and tradition tells us that he labored first with his father as a wool stapler and a butcher, and afterward as a schoolmaster and an attorney's clerk. The story that he was a butcher rests only on the relation of an old parish clerk, born too late to have any personal knowledge of the matter. That Shakespeare had more than a layman's knowledge of law, his plays afford evidence, the weight of which cannot be dissipated by the plea of the universality of his genius. Upon the authority of a tradition recorded by the Rev. Richard Davies, who died in 1708, Shakespeare was "much given to all unlikelihoods in stealing venison and rabbits." In his roivings he had fallen in with Anne Hathaway, the daughter of Richard Hathaway, a yeoman of Shrottery, a village near Stratford. This young woman, who was eight years older than Shakespeare, bore a daughter in May, 1583, of which he assumed the paternity by marrying the mother at some time after Nov. 28, 1582, at which date the bishop of Worcester granted a license for the marriage of "William Shagspere one thone partie, and Anne Hathwey of Stratford in the dioces of Worcester, maiden," upon "once asking of the bannes," the bride-

groom being at that time 18 and the bride 26 years old. Thus did Shakespeare find himself, the son of a ruined man, without a settled occupation, and lacking three years of his majority, a prospective father and the husband of a woman old enough to be his father's wife. We should not lightly pass over circumstances which he remembered long and sadly, as we learn from his sonnets, and by a passage in one of his plays ("Twelfth Night," act ii. sc. 4), written 18 years after, in the height of his reputation and his prosperity. How and where he lived with his wife, whether in Stratford or Shrottery, we do not know. Nor has it been discovered how long he lived with her; but Hamnet and Judith, twin children of William and Anne Shakespeare, were baptized at Stratford, Feb. 20, 1584-'5; after which we hear of no other offspring of this ill-starred union.—We know nothing positively of Shakespeare from his birth until his marriage, and from that date nothing but the birth of his three children until we find him an actor in London about the year 1589. Play-going was a favorite diversion in the days of Elizabeth, and in fact may be regarded as a means of popular amusement and instruction, which then supplied the place of the popular lecture, the light literature, and the newspaper of our day. The best players performed of course at London; but strolling bands went through the rural districts, and even the metropolitan companies sometimes travelled into the provinces. During Shakespeare's boyhood plays had often been performed at Stratford; and there is some reason to believe that several of his seniors among the youth of Stratford had gone upon the London stage. Besides his urgent need, his consciousness of dramatic ability, and his certainty of finding acquaintances in the London theatres, another motive has been furnished him by tradition. It is said that his poaching propensities led him to steal a deer from Sir Thomas Lucy of Charlecote, near Stratford, and that, being harshly treated by the knight, he revenged himself by a lampooning ballad which he stuck upon the gates of the park he had violated. The ballad, as it has come down to us, is coarse, though clever; it irritated Sir Thomas so much that he redoubled his persecution of Shakespeare, and being the most important man in that vicinity, he drove the poor lad out of Stratford. This story, first told by Rowe, on the information of Betterton the actor, in "Some Account of the Life of William Shakespeare," prefixed to his edition of the poet's works, is sustained by independent tradition. It has been attacked with vigor and ingenuity by those who would fain have the world believe that the boy Shakespeare neither stole deer nor wrote coarse lampoons; but its credibility has never been materially impaired, and it is certainly supported by the sharp cut at Sir Thomas Lucy in the opening of the first scene of "The Merry Wives of Windsor." Shakespeare probably arrived

in London in 1585 or 1586; the earlier date best according with all the facts and circumstances to be considered. One tradition says that he was received into the company at first in a very mean rank; and another that his earliest position was that of "a servitor," which is probable. Young players were then apprenticed; he would have been expected to begin as an apprentice; and apprentices were then called servants. Tradition also says that he began his London life by holding horses at the playhouse doors, a story which has neither probability nor concurrent testimony to support it. Be this as it may, his rise to eminence was rapid; though not as an actor, for he seems never to have risen above the position known on the French stage as "general utility." We are tolerably well informed by contemporary writers as to the performances of the eminent actors of that time, but of Shakespeare's we read nothing. There is a tradition that he played the Ghost in his own "Hamlet;" and it is recorded by Oldys that one of his younger brothers, who lived to a great age, when questioned in his last days about William, said that he could remember nothing of his performances but seeing him "act a part in one of his own comedies, wherein, being to personate a decrepit old man, he wore a long beard, and appeared so weak and drooping, and unable to walk, that he was forced to be supported and carried by another person to a table, at which he was seated among some company, and one of them sung a song." If this story may be believed, we know that Shakespeare played Adam in "As You Like It." There is a tradition also that he played kingly parts, for which his fine person and graceful bearing fitted him. We learn from Ben Jonson's own edition of his comedies (folio, 1616) that Shakespeare played a principal part in "Every Man in his Humour" when it was first performed in 1598, and also in "Sejanus" when it was brought out in 1603; but what characters he sustained in these plays we do not know. Shakespeare's pen seems to have been soon employed, but not at first in purely original composition. In his time there was an inordinate craving for new plays. Public taste was rapidly improving; and plays the subjects of which were popular were rewritten again and again to meet the demands of an advancing standard of criticism. Young lawyers and poets produced plays rapidly. Each theatrical company not only "kept a poet," but had three or four in its pay; and there was hardly a theatre which could not boast of as many of its actors who could write as well as act. There was a never-ceasing writing of new plays and furnishing up of old ones. Two, three, and even half a dozen playwrights were employed upon one drama, when haste was necessary for the theatre, or when the junto needed money, which was almost always. It was upon this field of labor that Shakespeare entered; not

seeking from it fame, but fortune; not consecrating himself to literature, but working for the wherewithal to return to the Stratford which he had left almost a fugitive to live there like a gentleman, under the very noses of the Lucys. It has been generally believed that Shakespeare on his arrival in London joined at once the company which played at the Blackfriars theatre, known as the lord chamberlain's servants, and that he wrote for no other. But although there is no doubt that he soon became engaged with that company, and although it is quite possible that he never played in any other, there seems to be reason for believing that he began his career as a dramatist by writing in company with Robert Greene and Christopher Marlowe, who were already playwrights of established reputation, and who wrote chiefly for a company known as the earl of Pembroke's servants. In conjunction with them he appears to have written a part of the "Taming of a Shrew," of "The First Part of the Contention betwixt the Two Famous Houses of York and Lancaster," and of "The True Tragedy of Richard Duke of York," which he afterward rewrote alone, and brought out as his own, as "The Taming of the Shrew" and the second and third parts of "King Henry VI." He soon obtained that degree of eminence which insures the enmity of surprised, eclipsed, and envious contemporaries. The first public notice of him that has yet been discovered is the bitter sneer of an unworthy, dying, disappointed rival. Robert Greene, writing from the fitting deathbed of a grovelling debauchee, warns three of his literary companions to shun intercourse with actors, whom he styles "puppits that speake from our mouths, those anticks garnished in our colours." He goes on to say: "Yes, trust them not: for there is an upstart crow beautified with our feathers, that with his Tygres heart wrapped in a players hide, supposes he is as well able to bombast out a blanke verse as the best of you; and beeing an absolute *Johannes Fac-totum*, is, in his own conceyt, the only Shake-scene in a countrey." The allusion here to Shakespeare is unmistakable; the words "Tygres heart," &c., are slightly altered from a line which is found both in the "Third Part of King Henry VI." and in "The True Tragedy;" and the former play is plainly indicated as one of those in which the upstart crow is beautified with the feathers of Greene and of the friends whom he addresses, Marlowe, Lodge, and Peele. The letter in which this exhortation occurs was published in 1592, shortly after the writer's death, under the direction of his friend Henry Chettle. It gave offence to Marlowe and Shakespeare, as we know from a pamphlet published by Chettle three months after, in which he says: "With neither of them that take offence was I acquainted, and with one of them [Marlowe] I care not if I never be; the other [Shakespeare] . . . I am as sorry as if the original fault had

beene my fault, because myselfe have seene his demeanor nor lesse civill than he exlent in the qualitie he professes; besides divers of worship have reported his uprightness of dealing which argues his honesty, and his facetious grace in writting that approves his art." Thus we find Shakespeare at the age of 28, only between six and seven years after his departure from Stratford, in possession of the regard of his equals, the respect of his superiors, the admiration of the public, and the consequent jealous hate of his inferiors. From this time to the end of his career in London our knowledge of his life is confined almost exclusively to the production of his plays and poems; and the date at which these were written has in most cases to be inferred or conjectured. Before this time, in addition to his share in the old plays already named, and perhaps some others which are lost, including an older form of "The First Part of King Henry VI.," he had quite surely written "Titus Andronicus," "Love's Labor's Lost," "The Two Gentlemen of Verona," "The Comedy of Errors," and perhaps a part of an early and unpublished form of "Romeo and Juliet," and a part of "A Midsummer Night's Dream." In 1593 appeared his first published poem, "Venus and Adonis," in which the glow of youthful ardor is chilled, but not extinguished, by the cold and elaborate style in which, in imitation of the poets most in vogue at that time, he, going thus the way of all young authors, studiously wrote. This poem is filled with evidences of an intimate knowledge and genuine love of nature, and, apart from the attractiveness of its subject, it is not surprising that five editions of it were called for within nine years. It was dedicated to the earl of Southampton, who loved literature and the drama, and encouraged men of letters and even players. It is said that the poet received from him £1,000 as a free gift. As this sum at that time was equal to about \$30,000 in America to-day, the amount has probably been much exaggerated, possibly by the addition of a cipher. Rowe, who first told this story, says that Southampton gave the money that Shakespeare "might go through with a purchase which he heard he had a mind to;" and it has been reasonably conjectured that this purchase was an interest in the company to which Shakespeare attached himself soon after his arrival in London, and in which he became a principal owner. Mr. John Payne Collier produced in 1835, as one of several of a similar nature which he had discovered among the manuscripts of the earl of Ellesmere at Bridgewater house, a certificate dated "Nov'r 18, 1589," in which Shakespeare's name appears as the 12th in a list of 16 "sharers in the Blacke Fryers play-house." This document has been pronounced spurious by some of the most eminent and respectable palæographers and English scholars in England. If it is genuine, and Shakespeare was indebted to his noble patron for any share in the company, the

dedication was an acknowledgment of the gift, and not the contrary. In any case we may be sure that the poem was written some years before it was printed. In the dedication Shakespeare calls it "the first heir of his invention," and promises his patron to take advantage of all idle hours until he has honored him with some graver labor. In 1594 Shakespeare published "Lucrece," which he also dedicated to Southampton, saying: "The love I dedicate to your lordship is without end. . . . What I have done is yours; what I have to do is yours; being in part all I have devoted yours." Between 1592 and 1596 he probably wrote, and in this order, "Richard III.," "All's Well that Ends Well" (which seems to have been first called "Love's Labor's Won"), "A Midsummer Night's Dream" in its latest form, "King Richard II.," and "The Merchant of Venice." With the two last named plays begin the indications of that mental development of their author which has been called "the middle period" of his genius. "King John," the rewritten "Romeo and Juliet," "The First and Second Parts of King Henry IV.," "The Merry Wives of Windsor," "As You Like It," "Much Ado about Nothing," "King Henry V.," "Twelfth Night," and "Hamlet" (founded probably upon an older play) seem to have succeeded each other rapidly from 1596 to 1600 inclusive. "The Second Part of King Henry IV." is perhaps the most complete existing presentation of his many-sided genius. It is surpassed in some one respect by several of the comedies and tragedies; but in no other single play does the supremacy of his powers as poet, dramatist, philosopher, wit, and humorist so manifestly appear. In this history the character of Falstaff attains its highest development. The great tragedies were the fruit of the first decade of the 17th century. As several of them were not printed until the publication of their author's collected works after his death, the order of their production is not easily determinable. They, with two comedies, were probably produced in the following order: "Troilus and Cressida," "The Taming of the Shrew," "Measure for Measure," "Othello," "King Lear," "Macbeth," "Julius Cæsar," "Antony and Cleopatra," "Coriolanus;" but the last named tragedy was not improbably written after 1610. "King Lear," the grandest exhibition of its author's genius, may be safely attributed to the year 1605, when Shakespeare was 40 years old. Between 1610 and 1613 "Cymbeline," "Timon of Athens," "The Winter's Tale," "The Tempest," and "King Henry VIII." were produced; and about the latter year Shakespeare ceased to write. It is remarkable that among his very latest productions were two plays, in one of which, "The Tempest," he preserves the unities of time and place with classic tenacity, while in the other, "The Winter's Tale," he sets them at naught with a recklessness which has no parallel even in his pages. "Pericles,"

published in his lifetime as his, shows marks of his latest style, which increase in frequency toward its close; it is doubtless the work of another hand which he undertook to embellish. Of "The Two Noble Kinsmen," published in 1634 as by Fletcher and Shakespeare, there can be hardly a question that he was in part the author; but it was probably an old play to which he made additions, and to which again Fletcher, after Shakespeare's death, put a modifying hand. In addition to the works which have been enumerated, he wrote "A Lover's Complaint," a very charming amatory elegy, which bears the marks of his style in the earlier part of his "middle period;" some minor pieces, which were embodied in a miscellany called "The Passionate Pilgrim;" and his sonnets. These sonnets, though deformed with occasional conceits, far surpass all other poems of their kind in our own language, or perhaps in any other. To whom they were written, and in whose person, is among the most difficult of unsolved literary problems. They were published in 1609 with a dedication by the publisher to a "Mr. W. H.," whom he styles their "onlie begetter;" and who this begetter was no man has yet been able satisfactorily to show. Most of them are addressed in terms of the warmest endearment to a beautiful young man; many of them reproach, in the words of a man who is wroth with one he loves, a beautiful and faithless woman; a few belong to the class called "occasional." It has been ingeniously argued by Mr. Boaden that the gentleman so unceremoniously addressed by a bookseller as Mr. W. H. was William Herbert, earl of Pembroke; but Chalmers had almost as much reason for his notion that he was Queen Elizabeth in doublet and hose. Conjecture upon this subject has been various and futile; and it has been reasonably supposed, in the words of the Rev. Alexander Dyce, one of the most accomplished, learned, and candid of Shakespeare's commentators, that "most of them were composed in an assumed character, on different subjects and at different times, for the amusement, if not at the suggestion, of the author's intimate associates." This opinion as to their origin is sustained by the first quotation from Francis Meres given below. But the sonnets themselves forbid us to accept this theory as satisfactory.—Meagre as this record is, compared with the eminence of its subject, we have nearly approached the limits of our knowledge of Shakespeare's life. A century ago George Steevens wrote: "All that is known with any degree of certainty concerning Shakespeare is, that he was born at Stratford-upon-Avon, married and had children there; went to London, where he commenced actor, and wrote poems and plays; returned to Stratford, made his will, died, and was buried." The assiduous researches of 100 years have discovered little more than this. The antiquaries have found his name in a few public documents

and private letters, telling of the purchase of lands and tithes, the leasing of houses, and the borrowing of money. The notion for a long time prevailed, and to a certain extent still prevails, that Shakespeare was unappreciated and neglected in his lifetime, and owes his fame to the discovery of his genius by his posthumous critics. The fact is quite otherwise. We have seen what his reputation was both as an author and a man in 1592. His "Venus and Adonis," published in the next year, had run through five editions by 1602. Both it and "Lucrece" are highly extolled by contemporary writers. Spenser alludes to him in "Colin Clout," written in 1594, as one

Whose muse, full of high thought's invention,
Doth like himselfe heroically sound.

Francis Meres, in his "Palladis Tamia" (1598), said that "the sweete wittie soul of Ovid lives in mellifluous and honey-tongued Shakespeare; witness his 'Venus and Adonis,' his 'Lucrece,' his sugred sonnets among his private friends." "As Plautus and Seneca are accounted the best for comedy and tragedy among the Latines, so Shakespeare among the English is the most excellent in both kinds for the stage." And this was before his greatest works were written. Meres adds: "As Epilus Stolo said that the Muses would speake with Plautus' tongue, if they would speake Latin, so I say that the Muses would speake with Shakespeare's fine filed phrase if they would speake English." We know, too, that his plays were as attractive to the public as they were satisfactory to those critics who were not his rivals. Leonard Digges, born in 1588, tells us, in verses not published till 1640, that when the audience saw Shakespeare's plays they were ravished and went away in wonder; and that, although Ben Jonson was admired, yet when his best plays would hardly bring enough money to pay for a sea-coal fire, Shakespeare's would fill "cock-pit, galleries, boxes," and scarce leave standing room. Wealth was the sure result of such success; and so we find that as early as 1597 he had bought a fine mansion in his native town, built originally by Sir Hugh Clopton in the reign of Henry VII., and known as "the great house," and afterward as New Place. It was the largest and best house in Stratford, and as such, when in the possession of Shakespeare's granddaughter, Mrs. Nash, afterward Lady Barnard, was occupied by Queen Henrietta Maria in 1643, during the civil war. In 1597, also, Shakespeare opened a negotiation for the purchase of a part of the lease of the tithes of Stratford, which however was not perfected for some years, when he invested a sum equal to about \$13,000 in this public security. He otherwise increased in substance, and, like his own "Justice Shallow," had "land and beeves." In 1596 John Shakespeare obtained from the heralds' college a "confirmation" of an alleged previous grant of arms, in which confirmation it is said that

the grantee's "parents and late antecessors" "were for their valiant and faithful services advanced and rewarded of the most prudent prince Henry the Seventh." But no record of such advancement, or of the original grant of arms, has been discovered; and as these allegations were true of William Shakespeare's "antecessors" on the mother's side, it has been reasonably conjectured that the "confirmation" of arms was applied for by John Shakespeare at his son's instance, and procured by his influence. Tradition tells us that Shakespeare's memory clung to Stratford in the midst of his metropolitan triumphs and successes, and that he visited his family once a year. His townsmen respected and looked up to him, and in some cases leaned confidently upon his good offices in the way of influence and the advancement of money. We know nothing of his intercourse with actors and men of letters in London, save that he won gruff Ben Jonson to say in his "Discoveries:" "I loved the man, and do honor his memory on this side idolatry as much as any." And indeed, according to the tradition furnished by Betterton to Rowe, Jonson was indebted to Shakespeare for the reception and performance of his first play at the Blackfriars theatre. It had been tossed aside as the production of an unknown writer, when Shakespeare read, admired, and recommended it. Fuller says in his "Worthies" that the two friends had many "wit combats" together, in which he compares Jonson to "a Spanish great galleon," "solid but slow in his performances," and Shakespeare to an "English man-of-war, lesser in bulk but lighter in sailing." It has been supposed that these encounters took place at the Mermaid tavern, where a club met which Sir Walter Raleigh had founded, and of which Jonson, Beaumont, Fletcher, Selden, Donne, and others of their sort were members. There is no evidence whatever to show that Shakespeare ever met with this club; but it is extremely improbable that he was not a member of it. There is a tradition that King James was so much his admirer that he wrote him "an amicable letter" in autograph. It is not very improbable that James should have done so; and there is evidence of some weight to show that the letter was in the possession of Sir William Davenant, although at the beginning of the last century it had been lost.—Shakespeare is supposed to have abandoned the stage about 1604, and to have returned to Stratford to live at some time between 1610 and 1613. No record or noteworthy tradition of any event of importance or interest in this part of his Stratford life has reached us. Rowe says that he spent it "in ease, retirement, and the conversation of his friends," who were "the gentlemen of the neighborhood." We have no account of the manner of his death except the following entry in the diary of the Rev. John Ward, who was appointed vicar of Stratford in 1662, nearly 50 years after the

event to which it relates: "Shakespeare, Drayton, and Ben Jonson had a merie meeting, and it seems drank too hard, for Shakespeare died of a feavour there contracted." It is not impossible that this piece of gossiping tradition is true. Shakespeare was buried on the second day after his death, on the north side of the chancel of Stratford church. Over his grave there is a flat stone with this inscription, said to have been written by himself:

Good frend for Iesus sake forbear
To digg the dust enclosed heare:
Blest be ye man y^e spares thes stones,
And curst be he y^e moves my bones.

By whomsoever these lines were written, they have happily been effectual in keeping at Stratford what might otherwise have been carried to Westminster. Against the north wall of the chancel is a monument which was erected before 1623, and in which the poet's bust appears under an arch; his right hand holds a pen, and he appears to be in the act of writing upon a sheet of paper placed on a cushion before him. This bust, which is of life-size, was originally colored after nature. The eyes were of light hazel, the hair and beard auburn. The same Rev. Mr. Davies who records his "unluckinesse in stealing venison and rabbits," also writes that he died a papist; but, considering the extreme puritanical notions then prevalent, a very moderate degree of high churchmanship would be likely to be stigmatized among the people as papistry, especially in an actor. His works are imbued with a high and heartfelt appreciation of the vital truths of Christianity, without leaning toward any form of religious observance or of church government, or any theological tenet or dogma. His character seems to have been one of singular completeness, and of perfect balance. An actor at a time when actors were held in the lowest possible esteem, he won respect and consideration from those who held the highest rank and station; a poet, he was yet not only thrifty but provident. Surpassing all his rivals among his social equals, he was, after the recoil of the first surprise, loved by all of them. "Sweet" and "gentle" are the endearing epithets which they delighted to apply to him. His integrity was early noticed, as has already been remarked; and Jonson, in his "Discoveries," says he was "indeed honest, and of an open and free nature." In person he appears to have been no less agreeable than in mind. Aubrey heard that he was "a handsome, well shapt man." With this report the bust at Stratford, and the portrait engraved by Droeshout for the first collected edition of his works, agree. They are the only existing authentic portraits of him; and hard and poorly drawn as the latter is, there is a conformity between the two which sustains the authenticity of both. Both show a somewhat unusual length of upper lip; otherwise the features are remarkably well shaped and proportioned, and the head is

large and symmetrical. Many other portraits, some on canvas, two in bust form, and even lately one in the shape of a plaster mask, have been brought forward as representations of Shakespeare; but, whatever their pretensions, all of them fail just where the pedigree of the so-called Chandos portrait fails, in a direct connection with the poet.—Such brief criticism as could be here passed upon his works would be superfluous, almost impertinent. By the voice of the whole civilized world his name is “the first in all literature;” in imagination, in fancy, in knowledge of man, in wisdom, in wit, in humor, in pathos, in strength, in versatility, in felicity of language, in the music of his verse, and in that mysterious power which fuses all these separate powers into one, and makes them a single means to a single end, he stands unapproached, and seemingly unapproachable. According to the custom of his time, his dramas were founded upon others, the subjects of which were favorites with the public, or upon popular tales, or passages in history. But in the interweaving of two stories into one plot (as in “The Merchant of Venice”), and in the elaboration of a bald and barren subject, he exhibited a constructive faculty not inferior to his other gifts. He did not hesitate to avail himself of the very language of the chronicler or novelist to whom he went for incidents; but in passing through his mind it was transformed from perishable prose into imperishable poetry. His chief excellence is in the unity and consistent action of his characters. He gave each one an individual soul; they speak their own thoughts and feelings, not his. In this respect his power seems almost supernatural.—Unlike Dante, unlike Milton, unlike Goethe, unlike the great poets and tragedians of Greece and Rome, Shakespeare left no trace upon the political or even the social life of his era. Among his contemporaries and countrymen were Raleigh, Sidney, Spenser, Bacon, Coke, Camden, Cecil, Hooker, Drake, and Inigo Jones; and yet there is no evidence, even traditional, that he had any acquaintance with either of these men, or with any others of less note among the statesmen, scholars, soldiers, or artists of his day. In making his will Shakespeare left his wife (who survived him seven years), by an interlined bequest, only his “second best bed with the furniture.” This looks like a slight; but his wife was amply provided for by her dower right, and the knowledge of this might very probably cause him to pass over her at first unnamed. Yet in a will containing so many small bequests, the interlineation of a wife’s name cannot but be regarded as evidence of some lack of consideration. His family became extinct in the third generation. His son Hamnet died in 1596 at the age of 11 years. His elder daughter married a physician, Dr. John Hall, to whom she bore one daughter, who married Thomas Nash, and after his death Sir John Barnard, and died childless (1670).

His second daughter, Judith, married Thomas Quiney, and had three children, who all died without issue. Upon the death of Lady Barnard, New Place was sold. It passed again into the hands of a Sir Hugh Clopton, and finally became the property of the Rev. Francis Gastrell, who in 1759, having quarrelled with the town magistrates about assessments, razed the building to the ground, after having in 1756 cut down the mulberry tree planted by Shakespeare, because he was annoyed by the pilgrims who came to visit it. The house in Henley street has at last been purchased by an association which has had it restored as far as possible, and placed it in the hands of proper keepers.—Of Shakespeare’s 37 plays, 17 were printed separately in quartos, in almost every instance, it would appear, without his coöperation, and in many instances from copies surreptitiously obtained. The text of most of these quarto copies is very corrupt and imperfect. In 1623 two of his fellow actors, John Heminge and Henry Condell, superintended the publication of the first collected edition of his “Comedies, Histories, and Tragedies,” from which however “Pericles” was omitted. This volume, known as the first folio, contains the only authentic text of Shakespeare’s plays. But its authority is grievously impaired by the careless manner in which it was printed, and by the fact that in some cases it was put in type from the surreptitious and imperfect quartos which it was intended to supersede, and the errors of which it not infrequently perpetuates; but it corrects vastly more errors than it makes and repeats, and it supplies serious deficiencies, although it leaves some to be supplied. Plainly, too, most of the quarto copies from which it was printed had been used as stage copies by Shakespeare’s company, and thus received many corrections which were at least *quasi* authoritative. Of the text of 20 of the plays it is the only source. In 1632 a second edition of the collected plays appeared. It corrected the text of its predecessor in a few passages, corrupted it in many, and modernized it in some. It is of no authority. A third edition appeared in 1664 (some copies are dated 1663), which is chiefly noticeable from its containing “Pericles” (as to which see above), and six spurious plays attributed to Shakespeare by booksellers in his lifetime, but rejected by his friends and fellow actors: “The London Prodigal,” “Thomas Lord Cromwell,” “Sir John Oldcastle,” “The Puritan Widow,” “A Yorkshire Tragedy,” and “Locrine.” A fourth folio was published in 1685. Original copies of the folio of 1623 are eagerly sought at very high prices by Shakespearean students and collectors. They are rare, and the condition and recent history of each one is known and recorded. The last three sales (down to 1875) of fine copies were for £525, £585, and £716 respectively. But even these were not absolutely perfect according to bibliographic standard. Should a copy be found in that

condition, it would probably fetch not less than £1,000. The folio of 1623 was reprinted with a tolerable approach to accuracy in London in 1808; a very beautiful reprint, in which no errors have been detected, was put forth by Lionel Booth (London, 1862-'4); and a photo-zincographic facsimile, made under the care of Mr. Howard Staunton, appeared in 1865. The quartos have also been reissued in facsimile at various dates under the care of Mr. J. O. Halliwell; and the two remarkable quartos of "Hamlet" (1603 and 1604), in the possession of the duke of Devonshire, were reprinted together on parallel pages, as "The Devonshire Hamlets" (London, 1860), edited by Mr. Samuel Timmins. Justin Winsor, superintendent of the Boston public library, has published "Bibliography of the original Quartos and Folios of Shakespeare, with particular reference to Copies in America, with 62 Heliotype Facsimiles" (Boston, 1875).—The text of Shakespeare's works, excepting his poems, was left in so corrupt a state by the early printers, that, the author's manuscripts having perished, it needed much editorial care to bring it even into a tolerably sound condition. This subject has engaged the attention of critics and scholars for more than a century and a half, and has produced a literature in which much learning, ingenuity, and philological and even philosophical speculation are mingled with ignorance, stupidity, frivolity, and bad temper. When to the works of the editors and textual critics are added those of the philosophical and the exegetical, and the illustrators, we have a library in itself. The best index to Shakespearian literature yet published is that of Franz Thimm (12mo, London, 1865; 2d ed., 1872), which has superseded that of P. H. Sillig (8vo, Leipsic, 1854); but the former is often incorrect, and is imperfect even up to its date; while that published by J. O. Halliwell (London, 1841) is very incomplete. A nearly perfect and generally correct catalogue of Shakespeariana is to be found in Bohn's edition of Lowndes's "Bibliographer's Manual" (London, 1864); but it is badly arranged, and deformed by many important errors in names, dates, and titles. A complete and accurate critical catalogue of Shakespeariana is still a desideratum.—The editions of Shakespeare's works which, for their text or comments, are worthy of notice are: Nicholas Rowe's (7 vols. 8vo, London, 1709), the first in which the text was submitted to collation and revision; Alexander Pope's (6 vols. 4to, 1725), probably the worst ever published; Lewis Theobald's (7 vols. 8vo, 1733), in which a great advance was made in the rectification of the text; Sir Thomas Hanmer's (6 vols. 4to, Oxford, 1744); Bishop Warburton's (8 vols. 8vo, London, 1747); Dr. Johnson's (8 vols. 8vo, 1765), the value of which is in inverse proportion to the reputation of its editor; Edward Capell's (10 vols. 8vo, 1767), most laboriously and carefully edited, but with little judgment or taste;

Johnson's edition with additional notes by George Steevens (11 vols. 8vo, 1773); the same with additional notes by Isaac Reed (15 vols. 8vo, 1793); Edmund Malone's edition, a most important one (11 vols. 8vo, 1790); Isaac Reed's, an enlargement of that of 1793, with the notes and readings of various commentators, commonly called the first *variorum* (21 vols., 1813); Malone's second edition, completed and superintended after his death by James Boswell, jr. (21 vols., 1821), "the" *variorum*; Samuel Weller Singer's (10 vols. fcp. 8vo, Chiswick, 1826), an edition marked by all the traits of the critical school of the last century, but very popular from its beauty of typography and its judicious selections from the notes of previous editors. Much had thus far been done to correct and illustrate the text of Shakespeare; but it had suffered almost as much from the presumption, the perverseness, and the narrow precision of his editors and commentators, as it had profited by their laborious investigation of the literature and the manners of his time. The critical spirit of the last century was narrow and oppressed with deference to classical models. The authoritative position of the first folio was little regarded, and its readings were set aside without cause as well as with cause, at the caprice of the editor. But the minds of men had come more and more under the influence of Shakespeare's genius. It was found that he was not to be judged by the standards of the schools, but that he was a law unto himself. During the first quarter of the present century there was a growing dissatisfaction with the results of the editorial labor of the last upon the works of Shakespeare. The result was a new school of commentators and new editions of the plays. First in point of time, and most nearly absolute in deference to the first folio, was the pictorial edition of Mr. Charles Knight (8 vols. 8vo, London, 1839-'41; revised ed., 1867). This was the extreme recoil of the pendulum. It was immediately followed by the edition of Mr. John Payne Collier (8 vols. 8vo, 1841-'4). Mr. Collier worked in the spirit of an antiquary rather than a critic, and made much of readings derived from the rarest and most inaccessible quarters. He opposed conjectural emendation with a bigotry which rivalled Mr. Knight's Quixotic championship of the first folio, and often set reason at naught in favor of "the oldest authority." A judicious eclectic use was made of the labors of Mr. Knight and Mr. Collier by Gulian C. Verplanck, who prepared an edition (3 vols. 8vo, New York, 1847), to which he contributed a large amount of original matter distinguished for soundness of judgment and elegance of taste. An edition published under the direction of the Rev. H. N. Hudson (11 vols. 12mo, Boston, 1850-'57) is noticeable chiefly for the true appreciation, subtle thought, and manly vigorous style of the essays introductory to each play. In 1853 Mr. J. O. Halliwell began the publication of a stu-

pendous edition, in 20 vols. folio, which was intended to present all of interest that has been discovered or written for the illustration of Shakespeare down to the present day. This great undertaking was several years in attaining a completion which fell somewhat short of the editor's expectations. Mr. Halliwell has not done much for the correction of the text; and the same is true of Mr. Howard Staunton's pictorial edition, in which much of Mr. Knight's matter has been used. One of the most judicious editions ever published is that of the Rev. Alexander Dyce (6 vols. 8vo, London, 1850-58), of which a second edition (9 vols. 8vo, 1864-7) and a third (1875) have appeared, the last being posthumous, and each showing many and noticeable changes from the text of its predecessor. The edition of Mrs. Mary Cowden Clarke (2 vols. 8vo, New York, 1860) gives the text very carefully and judiciously. In his revisions Mr. Dyce availed himself largely of the next edition of the poet's works, prepared from a new recension and collation of the text, that of Mr. R. Grant White (12 vols. crown 8vo, Boston, 1857-62), which seeks to present the reader with all that is necessary to a critical study of the poet, and which is distinguished by its numerous and successful restorations of corrupted passages. The last complete edition of importance is that of Cambridge, edited by W. G. Clark and W. Aldis Wright (9 vols. 8vo, London and Cambridge, 1863-6), which gives all the readings of all the folios and all the quartos, and of all the editors, and the suggestions and conjectures of all the commentators whose labors are generally deemed worthy of consideration. In 1871 Mr. Horace Howard Furness began the publication of a great variorum edition, intended to include everything essential or even important as to its subject. The plays which have appeared, "Romeo and Juliet" and "Macbeth," have been received with marked approval by Shakespearian scholars.—Of the books written upon Shakespeare's life, text, and genius, forming a mass of which a very imperfect record of the mere titles fills 89 octavo pages in Sillig's book, mentioned above, only a few of the most noteworthy can be indicated here. "A short View of Tragedy; its original Excellency, and Corruption, with some Reflections on Shakespeare and other Practitioners for the Stage," by Thomas Rymer (8vo, London, 1693), is noticeable only as being the first book on this subject. But Dryden in his "Essay of Dramatic Poesy" (1668), and in the prefaces to "The Tempest" (1670) and "Troilus and Cressida" (1679), and the defence of the epilogue to "The Conquest of Granada" (1672), and Langbaine in his "Account of the English Dramatic Poets" (1691), had previously criticised Shakespeare's plays, the former very elaborately. Of subsequent critical works these are worthy of particular remark: "Shakespeare Restored, or Specimens of Blunders committed and unamended in Pope's Edi-

tion of this Poet," by Lewis Theobald (4to, London, 1726); "Miscellaneous Observations on the Tragedy of Macbeth, with Remarks on Sir T[homas] H[anmer's] Edition of Shakespeare; to which is affixed Proposals for a new Edition of Shakespeare with a Specimen," by Samuel Johnson (12mo, London, 1745); "Critical Observations on Shakespeare," by John Upton (8vo, London, 1746 and 1748); "The Canons of Criticism," by Thomas Edwards (London, 1748, and, with additions, 1765); "A Revisal of Shakespeare's Text," by Benjamin Heath (8vo, London, 1765); "Twenty of the Plays of Shakespeare, being the whole number printed in Quarto during his Lifetime, or before the Restoration; collated where there were different copies, and published from the originals," by George Steevens (4 vols. 8vo, London, 1766); "An Essay on the Learning of Shakespeare," by Richard Farmer, D. D. (8vo, London, 1767, and, greatly enlarged, Cambridge, 1767); "Notes and Various Readings of Shakespeare," by Edward Capell (4to, London, 1775, and, with important additions and "The School of Shakespeare," 3 vols. 4to, 1783); "Six Old Plays on which Shakespeare founded 'Measure for Measure,' 'Comedy of Errors,' 'Taming the Shrew,' 'King John,' 'King Henry IV.,' 'King Henry V.,' and 'King Lear,'" (2 vols. 12mo, London, 1779); "Comments on the Last Edition of Shakespeare's Plays," by John Monck Mason (8vo, Dublin, 1785); "A Dissertation on the Three Parts of Henry VI.," by Edmond Malone (London, 1792); "A Specimen of a Commentary on Shakespeare, containing: 1st, Notes on 'As You Like It;' 2dly, An Attempt to explain and illustrate various Passages on a new Principle of Criticism derived from Mr. Locke's Doctrine of the Association of Ideas," by Walter White (8vo, London, 1794); "An Apology for the Believers in the Shakespeare Papers which were exhibited in Norfolk Street, London," by George Chalmers (8vo, London, 1797), and "A Supplemental Apology for the Believers in the Shakespeare Papers" (1799; these volumes, with "An Appendix" published in 1800, in spite of the speciality of their titles, are filled with general comment and the results of careful investigation); "Illustrations of Shakespeare and of Ancient Manners," &c., by Francis Douce (2 vols. 8vo, London, 1807); "Characters of Shakespeare's Plays," by William Hazlitt (London, 1817); *Vorlesungen über dramatische Kunst und Literatur*, by August Wilhelm von Schlegel (3 vols. 8vo, Heidelberg, 1817; translated by J. Black, London, 1818); "Shakespeare and his Times," by Nathan Drake, M. D. (2 vols. 4to, London, 1817); "A Glossary, or a Collection of Words, Phrases, Names, and Allusions to Customs, Proverbs, &c., which have been thought to require Illustration in the Works of English Authors, particularly Shakespeare and his Contemporaries," by Archdeacon Narès (4to, London, 1822; and

edited by J. O. Halliwell and Thomas Wright, 2 vols. 8vo, 1859), a learned and accurate work; *Shakespeare's Vorschule*, edited, and accompanied with prefaces, by Ludwig Tieck (2 vols. 8vo, Leipsic, 1823 and 1829); "New Facts regarding the life of Shakespeare," by J. P. Collier (8vo, London, 1835); "New Particulars regarding the Works of Shakespeare," by the same (8vo, London, 1836); "On the Sonnets of Shakespeare, identifying the Persons to whom they are addressed, and elucidating several points in the Poet's History," by James Boaden (8vo, London, 1837); *Ueber Shakespeare's dramatische Kunst und sein Verhältniss zu Calderon und Goethe*, by H. Ulrici (8vo, Halle, 1839; translated, 8vo, London, 1846); "Shakespeare's Library, a Collection of the Stories, Novels, and Tales used by Shakespeare as the Foundation of his Plays," edited by J. P. Collier (8vo, London, 1840-'41; new and enlarged ed., by W. Carew Hazlitt, 1875); "Remarks on Mr. J. P. Collier's and Mr. Charles Knight's Editions of Shakespeare," by the Rev. Alexander Dyce (8vo, London, 1844); G. G. Gervinus, *Shakspeare* (4 vols., Leipsic, 1849-'50); *Shakspeare et son temps, étude littéraire*, by Guizot (8vo, Paris, 1852); "The English of Shakespeare," by George L. Craik (12mo, London, 1857); "A Critical Examination of the Text of Shakespeare," by William Sidney Walker (3 vols. 16mo, London, 1860). Mrs. Mary Cowden Clarke's "Complete Concordance" or verbal index to the dramatic works of Shakespeare, the product of almost incredible labor and patience, appeared in 1846, and is an invaluable aid to the critical study of the poet. The multitudinous publications of the Shakespeare society of London contain, among much that is either trivial or mere antiquarian rubbish, many volumes of valuable and well edited reprints of scarce old plays, of dramatic history, and of critical suggestions for the improvement of the text of Shakespeare. The "New Shakespeare Society" was established at London in 1874, under the directorship and chiefly by the exertions of the distinguished English scholar Frederick J. Furnivall. Its purposes and its publications thus far are more critical than those of the elder and extinct society.—Eminent among the philosophical critics of Shakespeare is Samuel Taylor Coleridge, who by his lectures and by his essays (see his "Friend" and his "Literary Remains") did more perhaps than any other one writer to bring about a profound and thoughtful appreciation of the poet's works. Mrs. Jameson's "Characteristics of Women, Moral, Poetical, and Historical" (2 vols. 8vo, London, 1832), as a minute and sympathetic analysis of Shakespeare's principal female characters, must ever rank high in this department of literature. The Rev. H. N. Hudson's "Lectures on Shakespeare" (2 vols. 12mo, New York, 1848) are remarkable for the same qualities, which appear in a higher degree in the essays in his edition of the works above no-

ticed. Those essays he has embodied with other kindred matter in "Shakespeare, his Life, Art, and Characters" (2 vols. 12mo, Boston, 1872). Mr. R. Grant White, in "Shakespeare's Scholar" (8vo, New York, 1854), published historical and critical studies of the poet's text, characters, and commentators, and an examination of Mr. Collier's folio of 1632, the conclusions of which were sustained by discoveries made in England five years afterward. The same writer, in his "Essay on the Authorship of the three Parts of King Henry the Sixth" (8vo, Cambridge, 1859, privately printed), has, by the general consent of Shakespearean scholars, settled that interesting and long mooted question "so far as criticism can do it." This essay was afterward embodied in its author's edition of the poet's works.—In 1852 Mr. J. P. Collier, who had previously brought forward many documents of ancient date in relation to Shakespeare, announced that he had become the possessor of a copy of the second folio edition of Shakespeare's plays (1632), which from the first page to the last contained "notes and emendations in a hand not much later than the time when it went to press." He published a history of his acquaintance with this volume, and detailed accounts, accompanied with comment, of its most plausible marginal changes in the text: "Notes and Emendations to the Text of Shakespeare's Plays, from early Manuscript Corrections in a copy of the Folio, 1632, in the Possession of J. Payne Collier, F. S. A." The sensation caused by this publication was widespread and profound. The majority of readers hailed it almost as a revelation from the tomb of Shakespeare himself; and it seemed for the moment as if all previous editions of his works had become waste paper. A small minority doubted and wondered, and a few stoutly protested. The critics on the one hand supported it enthusiastically, and on the other attacked it vigorously. It was found that the greater part of its corrections had been anticipated by the conjectural emendations of editors and verbal critics; and of the comparatively small remainder, there were very few which commanded the general assent of English scholars and students of Shakespeare. It was shown first in a paper in "Putnam's Magazine" (New York) for October, 1853, by R. Grant White, that the corrections, upon their own evidence, were made at so late a date as to have no authority from their antiquity. The folio having been placed for a time in the British museum, certain officers of that institution, including the eminent paleographer Sir Francis Madden, superintendent of the manuscript department, pronounced its marginal corrections spurious imitations of ancient handwriting, and announced that they had discovered partially erased guides in pencil, in modern handwriting, for the antique-seeming words in ink, and that in many instances the modern pencil writing appeared under that in

ink, which professed to be more than 200 years old. Upon this announcement, in July, 1859, in the London "Times," a fierce discussion arose, which continued for more than two years. It had for its subject not only the notorious folio, but all the manuscripts which Mr. Collier had brought to the notice of the public as containing contemporary notices of Shakespeare or his works, nearly all of which were pronounced forgeries by the same high authorities which condemned the folio. So extensive and so important a literary fraud had never before been detected. Toward the end of the last century a scapegrace named William Ireland professed to have discovered miscellaneous papers and legal instruments under the hand and seal of William Shakespeare, which were outrageous forgeries; but they were palpably spurious, and were quickly exposed, although they deceived many men of erudition for a time. The result of the examination and discussion in Mr. Collier's case has been to leave him with a damaged reputation both for judgment and veracity, his folio without a semblance of authority, and his manuscripts under the gravest suspicion, at the very least; although his accusers have not succeeded in making out all their case. Most of the corrections in this folio seem to have been made about 1675; but there is evidence which goes strongly to show that Mr. Collier is responsible for some of them. See "An Inquiry into the Genuineness of the Manuscript Corrections in Mr. J. Payne Collier's Annotated Shakespeare Folio, 1632, and of certain Shakespearian Documents likewise published by Mr. Collier," by N. E. S. A. Hamilton (4to, London, 1860); Mr. Collier's "Reply" to this volume (London, 1860); "A Complete View of the Shakespeare Controversy," &c., by C. Mansfield Ingleby, LL. D., with numerous facsimiles (8vo, London, 1861); and a thorough examination of the whole subject in "The Shakespeare Mystery," an article by R. Grant White in the "Atlantic Monthly" (Boston) for September, 1861.—Books upon themes directly or indirectly connected with Shakespeare multiply so fast that a complete list of them must be sought in the professed catalogues of Shakespeariana; but among the more recent the following deserve special mention: "A Letter on Shakespeare's Authorship of the 'Two Noble Kinsmen,'" by W. Spalding (8vo, Edinburgh, 1833); "Shakespeare's Puck and his Folk Lore," by William Bell (3 vols. 16mo, London, 1852-'64); "Remarks on the Differences of Shakespeare's Versification in Different Periods of his Life," by C. Bathurst (8vo, London, 1857); "A New Exegesis of Shakespeare and Interpretation of his Plays on the Principle of Races," (8vo, Edinburgh, 1859); "On the Received Text of Shakespeare's Dramatic Writings," by Samuel Bailey (2 vols. 8vo, London, 1862-'6); "Shakespeare no Deer Stealer," by C. Holte Bracebridge (8vo, London, 1862); "A Key to Shakespeare's

Sonnets," by C. Barnstoff, translated from the German by T. J. Graham (8vo, London, 1862); "Shakespeare's Home at New Place," by J. C. M. Bellevue (8vo, London, 1863); "Shakespeare Commentaries," by G. G. Gerwinus, translated from the German by F. E. Bunnett (2 vols. 8vo, London, 1863; 2d ed., with a valuable introduction on the study of Shakespeare by F. J. Furnivall, 1 vol., 1875); "An Historical Account of New Place," by J. O. Halliwell (privately printed, fol., London, 1864); Shakespeare jest books (under various titles), edited by W. Carew Hazlitt (3 vols. 16mo, London, 1864); "On Shakespeare's Knowledge and Use of the Bible," by Charles Wordsworth (8vo, London, 1864); "Shakespeare's Editors and Commentators," by W. R. Arrowsmith (8vo, London, 1865); "Shakespeare in Germany," by Albert Cohn (4to, London, 1865); "Notices of the Drama, . . . chiefly in the 16th and 17th Centuries," by William Kelly (8vo, London, 1865); "Memoirs of the Life of William Shakespeare, with an Essay toward the Expression of his Genius," &c., by R. Grant White (8vo, Boston, 1865); "Shakespeare's Delineations of Insanity," &c., by A. O. Kellogg (16mo, London, 1866); "Shakespeare's Sonnets never before Interpreted," by Gerald Massey (8vo, London, 1866; enlarged ed. of only 100 copies, with the title "The Secret Drama of Shakespeare's Sonnets Unfolded," 1872); "On Early English Pronunciation, with especial reference to Shakespeare and Chaucer," by Alexander J. Ellis (3 vols. 8vo, London, 1867 *et seq.*); "The Authorship of Shakespeare," by Nathaniel Holmes (12mo, New York, 1867); "The Mad Folk of Shakespeare," by John Charles Bucknill (12mo, London, 1867); "The Shakespeare Expositor, an Aid to the perfect Understanding of Shakespeare's Plays," by Thomas Keightly (16mo, London, 1867); "An Introduction to the Philosophy of Shakespeare's Sonnets," by Richard Simpson (16mo, London, 1868); "A Shakespearian Grammar," by E. A. Abbott (16mo, London, 1869; 2d ed., 1871); "Genealogica Shakespeariana," by George Russel French (8vo, London and Cambridge, 1869); "On the Authorship of Works attributed to Shakespeare," by C. Mansfield Ingleby (8vo, London, 1869); "Notes and Conjectural Emendations," &c., by P. A. Daniel (8vo, London, 1870); "The Sonnets of Shakespeare Solved," by Henry Brown (8vo, London, 1870); "Index to the Pages of William Sidney Walker," by Mrs. Horace Howard Furness (50 copies privately printed, 16mo, Philadelphia, 1870); "The Method of Shakespeare as an Artist," by Henry J. Ruggles (16mo, New York, 1870); "Shakespeare and Topography," by William Blades (8vo, London, 1872); "New Readings in Shakespeare," by Robert Cartwright (8vo, London, 1873); "Caliban, the Missing Link," by Daniel Wilson (8vo, London, 1873); "Body and Mind, an Inquiry into their Connection and mutual Influence, specially in reference

to Mental Disorders," by Henry Maudsley, including a profound essay on Hamlet (12mo, London, 1873); "Essays on Shakespeare," by Karl Elze, translated from the German by L. D. Schmitz (8vo, London, 1874); "Jottings on the Text of Hamlet, first Folio *versus* Cambridge Edition," by Hiram Corson, (8vo, Ithaca, 1874); "A Concordance to Shakespeare's Poems," by Mrs. H. H. Furness (8vo, Philadelphia, 1874); "Shakespeare's Centurie of Prayse," by C. M. Ingleby (8vo, London, 1874); "An Essay on the Authorship of . . . Henry VI.," by George L. Rives, a Cambridge university (England) prize essay, but founded on, and chiefly an abridgment of, Mr. Grant White's essay on the same subject (8vo, Cambridge, 1874); "Shakespeare Lexicon, a Complete Dictionary of all the English Words and Phrases," &c., by Alexander Schmidt (2 vols. 8vo, Berlin, 1874-5); and "Shakespeare, a Critical Study of his Mind and Art," by Edward Dowden (8vo, London, 1875). The Germans have taken a lively interest in this discussion; and indeed Shakespeare for 75 years has been almost as assiduously studied in Germany as in Great Britain and America. But there is no sufficient ground for the assertion that the Germans taught the English race to understand him. The best German thought of the day upon this subject is gathered in the *Jahrbuch der Deutschen Shakespeare-Gesellschaft*, edited by F. Bodenstedt and F. Leo (Berlin, 1865 *et seq.*). Shakespeare's works have been translated into all the languages of the civilized world, but best into German. The version of Schlegel and Tieck, which has been often reprinted, is probably the most perfect transfusion of thought from one form into another that ever was accomplished. A German version has recently been produced jointly by Bodenstedt, Freiligrath, Paul Heyse, Herwegh, and others (38 vols., Leipsic, 1868-'72). No adequate French translation has yet appeared. Three of importance have been made: the first by Le Tourneur (1776-'82), in which the poet's thought is often ludicrously perverted; the next by Francisque Michel (1839-'40); and the third by François Victor Hugo (1859-'65). Of these, the second is the most faithful and scholarly.—Shakespeare's name is found in the manuscripts of his period spelled with all varieties of letters and arrangement of letters which express its sound or a semblance of it; but he himself, and his friend Ben Jonson, when they printed the name, spelled it Shakespeare. In this form, too, it is found in almost every book of their time in which it appeared. Therefore, although he sometimes wrote it Shakspeare, there seems to be no good reason for deviating from the orthography to which he gave a sort of formal recognition. The spelling Shakspeare was long prevalent.

SHALE (Ger. *schälen*, to peel, to split), a rock composed of clayey sediments consolidated in layers which are fissile like the original clay,

but not often divisible into smooth sheets like the argillaceous slates. Beds of shale are common throughout the range of the secondary rocks, and constitute a large portion of some of the formations. They alternate with the sandstone and other strata of these formations, and in the coal measures are abundant in beds blackened by the carbonaceous matters intermixed with the clayey sediments. In the red sandstone groups they are commonly also red from oxide of iron, and in other formations they are olive, and sometimes green and variegated. They are soft and earthy, and are easily worn down into a muddy powder. By intermixture of carbonate of lime they become calcareous, and as the proportion of this increases they pass from calcareous shale to argillaceous limestone. Sand renders them arenaceous, and with excess of it they become sandstones. Carbonaceous matter renders them bituminous, and when the proportion is large the material is used for some of the purposes of coal. Shales of this character yield oil. (See COAL, and PETROLEUM.)

SHAMANISM, in a wide sense, all spirit worship connected with magic arts, but commonly only that of the north Asiatic races. The name is a corruption of the Sanskrit *gramana*, a Buddhist ascetic or mendicant. Shamanism is one of the earliest phases of religious life, and is met in various forms among all the savage races of the world. It is akin to or a mixture of fetichism, or the adoration of magic stones and trees, and other material objects considered as abodes of spirits, and sabaism, or the worship of the stars. Shamanic priests affect to know the secret of controlling the coming and departing of evil spirits. Their offices are generally called into requisition in cases of sickness or death, which most rude peoples ascribe to the presence or ill will of demons. In Siberia the priest usually sucks the part of the body of the patient which aches the most, and finally takes out of his mouth either a thorn, a bug, a stone, or some other object, which he exhibits as the cause of the complaint. The process is sometimes accompanied with beating of drums and blowing of horns, while the priest works himself into a state of trance and epilepsy. Similar practices are recorded in the Vedic literature of the Hindoos, and the historical extension of shamanism among the tribes of northern Asia runs parallel with the spread of Buddhism. It appears also that some of the ancient religious schisms among the Iranians were due to the prevalence of shamanism. Until the reign of Genghis Khan the Mongols were almost wholly given to similar magic and sorcery; but subsequently many of them passed over to lamaism, which is in a measure also a kind of shamanism, but infused with Buddhistic doctrines.

SHAMOKIN, a borough of Northumberland co., Pennsylvania, on Shamokin creek and the Northern Central and Philadelphia and Read-

ing railroads, 95 m. N. W. of Philadelphia; pop. in 1870, 4,320; in 1875, estimated by local authorities at 7,500. It contains many brick buildings, is lighted with gas, and is supplied with water by the Shamokin water company from a distance of about 4 m. It is situated in the middle coal field, and its principal business is the mining of anthracite coal. The product of the Shamokin region in 1874 was about 1,250,000 tons. The borough contains three founderies and machine shops, three banks, four public school houses with 21 departments and about 1,400 pupils, two private schools with about 150 pupils, two weekly newspapers, and ten churches.

SHAMROCK. See **OXALIS**.

SHAMYL (SAMUEL), a chieftain of the Caucasus, born at Aul Himry, in northern Daghestan, about 1797, died in Medina, Arabia, in March, 1871. In his youth he embraced the doctrines of Kasi-Mollah, an energetic mysticism founded on Sufism. Several tribes of Daghestan united in 1823, under the leadership of Kasi-Mollah, in a religious war against the northern infidels. In 1834, on the death of Hamsad Bey, the successor of Kasi-Mollah, Shamyl was chosen head of the sect. Having organized a sort of theocracy among the eastern Caucasian mountaineers, he began a warfare against Russia. In 1837 he defeated Gen. Ivelitch. At the storming of Akulgo by Gen. Grabbe in 1839 Shamyl was supposed to have perished, but he soon after suddenly reappeared. In 1844, after having foiled another Russian campaign, he completed the organization of his government, uniting numerous tribes hitherto hostile, made Dargo his capital, and established a code of laws and a system of taxation and internal communication. In 1845, Czar Nicholas having renewed the war, Shamyl was able to bring a large army into the field. After 1852, however, he lost to some extent the confidence of the mountaineers, and his attempts to bring the neighboring tribes into his confederation failed. The growth of religious indifference and political dissensions had begun to undermine his power, and he was able to take but little part in the Crimean war. After the peace of Paris, Russia attempted again the subjection of the Caucasus. Shamyl held out bravely for three years, but, weakened by the successive defection of many tribes, and discouraged by the

death of his eldest son, he was at last overpowered and taken prisoner at the siege of the mountain fort of Ghunib, Sept. 6, 1859. He was treated with respect by Alexander II., and after a short stay in St. Petersburg was assigned a residence at Kaluga, receiving a pension of 10,000 rubles. From here he removed in December, 1868, to Kiev, and in January, 1870, went to Mecca. (See **CAUCASUS**.)

SHANGHAI, or **Shanghai** ("approaching the sea"), a city and seaport of China, in the province of Kiangsu, on the left bank of the Wusung river, about 12 m. above its junction with the Yangtse-kiang, in lat. 31° 10' N., lon. 121° 30' E.; pop. variously estimated from 250,000 to 320,000. It stands in a fertile plain intersected by numerous streamlets, and consists of old Shanghai, which is enclosed by a wall and moat about 3 m. in circumference, and several suburbs. The walled town, which is entered by six gates, has narrow, filthy streets, and

Custom House, Shanghai.

most of the buildings are small and mean; but some of the guild halls and tea shops are fine specimens of Chinese architecture. Of its many temples, the largest is the *Ching-hwang-mian* (city and moat temple), on a rocky island in a serpentine sheet of water. The Roman Catholics have a large cathedral and the Baptists a church within the walls, and the American and London missionary societies have large schools. The foreign suburb, which is divided into three parts, the French, British, and American concessions, is laid out like a European city, with broad, paved, well lighted streets, and handsome houses and gardens. The Anglican church, club house, and masonic temple are among the principal buildings. Back of the quay, which has a bulwark of stone and stone jetties, stand the honges of the foreign merchants. In the British concession is a race course, and lower down are ship

yards, machine shops, and dry docks. Many square-rigged vessels lie at the foreign quays, and in front of the Chinese town the river is thronged with junks lashed close together. The population of the foreign suburbs in 1873 consisted of 62,844 resident Chinese, 5,566 Chinese employed in foreign honges, 9,957 boat population and vagrants, and 2,000 foreigners; total, 80,867. The climate of Shanghai is subject to sudden changes in spring and autumn, and pulmonary and rheumatic complaints are common. The day temperature in summer is from 80° to 93°, and in winter from 45° to 60°. From June to October heavy rains fall. Shanghai has a mint, and manufactures of silk, cotton, vegetable oils and oil cake, iron ware, glass, paper, and ivory goods. It is connected by the grand canal and the Yangtse-kiang and other rivers with a large part of the empire, and is visited annually by 5,000 or 6,000 canal and river boats, and by 1,500 or 1,600 coasting junks. Its foreign trade is also very large. The number of entrances in the foreign trade in 1872 was 2,111, tonnage 1,165,967; 940 vessels were British, 741 American, 135 Chinese, 127 German, and 47 French. The total value of foreign imports was \$82,169,694; of imports of native goods, \$61,549,673. The value of the total exports of native produce was \$45,504,851; of foreign products re-exported, \$50,880,627. The principal exports are tea, silk, cotton, straw braid and hats, mats, wool, skins, oil and oil cake, drugs, porcelain, and fans; imports, opium, treasure, grain, flour, manufactured goods, and coal. The value of the exports to the United States in 1874 was \$15,868,556, of which \$13,869,522 was in tea.—Shanghai was taken by the British in June, 1842, but was given up in 1843, after the ratification of their treaty with the Chinese, when it became one of the five ports opened to foreign commerce. In September, 1853, it was captured by the Taiping rebels, who soon evacuated it. In 1860-'62 it was again threatened by them, but was protected by the British and French. Its commerce declined in 1865-'6, but it is again increasing. It is now one of the 14 Chinese treaty ports.

SHANNON, a S. E. county of Missouri, intersected by Current river; area, about 1,150 sq. m.; pop. in 1870, 2,339, nearly all white. The surface is uneven, and partly occupied by pine forests. Mines of copper and iron are worked. The chief productions in 1870 were 7,243 bushels of wheat, 104,725 of Indian corn, 7,496 of oats, 9,045 lbs. of tobacco, 3,294 of wool, 25,129 of butter, and 4,812 gallons of sorghum molasses. There were 637 horses, 657 milch cows, 1,658 other cattle, 2,549 sheep, and 6,362 swine. Capital, Eminence.

SHANNON, the largest river of Ireland, rises at the foot of Mt. Cuileagh in the N. W. part of the county Cavan, flows S. W. for a few miles to Lough Allen, thence by a circuitous but generally S. course to Lough Derg, passing through Lough Ree, and thence S. S. W. to

Limerick, below which the river, here called the Lower Shannon, flows W. S. W. through a broad estuary to the Atlantic. Its total length is about 250 m. Portions of its course are very picturesque. Its largest affluent is the Suck, which enters it from the west between Loughs Ree and Derg; others are the Boyle, Fergus, Inny, Brosna, Mulkear, and Maig. The principal towns on its banks besides Limerick are Leitrim, Carrick, Athlone, and Killaloe. The tides in the estuary of the Shannon vary between 14 and 18 ft., and vessels of 400 tons can ascend as far as Limerick; the navigation has been improved throughout the entire length at a cost of about £500,000, and parliament in 1874 appropriated £300,000 for its further improvement; and canals connect it with many parts of Ireland.

SHANNY, the name of the marine spiny-rayed fishes of the blenny family, and the genus *pholis* (Flem.). They differ from the blennies proper in having the head without crests or tentacles; the body is elongated and compressed, with large pectorals, rounded caudal, ventrals under the throat and of two rays, and a single interrupted dorsal all along the back, simple and flexible; the skin is naked; mouth small, with large lips and semicircular opening; teeth in single series, numerous, small, and pointed; there is no air bladder; the stomach is thin, without cæcal dilatation, and the intestine simple without pancreatic cæca; aperture of oviduct between anus and urinary canal, and a tuft of papillæ around the seminal opening. The European shanny (*P. lævis*, Flem.) is rarely more than 5 in. long; the colors vary much, some being mottled with reddish brown, black, and white, and others uniformly dusky; the head over the eyes is rounded, from these the profile being nearly vertical, and between them a deep groove; the irides are scarlet, and the cheeks tumid; the eyes have movements independent of each other. They are abundant on the rocky coasts of England and France, keeping on the bottom, and hiding under stones at low tide to guard against voracious fishes and long-billed birds; the food consists of small mollusks and crustaceans; they spawn in summer; they are small, swim in shoals, and are of no value as food to man. The larger specimens have the habit

European Shanny (*Pholis lævis*).

of creeping out of water, by means of the ventrals, as the tide recedes, hiding in holes of the rocks, and there remaining until the tide again rises; they have been known to live 30 hours

in a dry box, and are very soon killed by fresh water. It is a matter of considerable physiological interest to ascertain how this fish is enabled to live so long a time out of water; it has no air bladder or rudimentary lung for the aëration of the blood; it is not known to have any special arrangement of the gills or accessory sac for retaining water; the gill openings are very large, just the opposite from the case in the eels and other fishes which live long out of water, and would permit the gills to become very soon dry and improper to circulate the blood. It must be remembered that the body is soft and scaleless; cutaneous respiration is very important in batrachians, and perhaps the necessary oxygenation of the blood is effected through the skin, as in the *synbranchus* of Surinam, when the gills are not in action, under the control of the par vagum nerve; perhaps also air may be swallowed, and intestinal respiration supply the necessary oxygen, as in *cobitis*. The gill openings, though large, may be accurately shut, and the bulging cheeks may thus retain sufficient water to prevent the desiccation of the gills, assisted probably by the skin as a respiratory organ.—The radiated shanny (*P. subbifurcatus*, Storer), found rarely on the coasts of Massachusetts and New York, is about 5 in. long, reddish brown above and yellowish white below, with three dark-colored bands passing backward from the eyes; the lateral line is subbifurcated, and there are filaments on the nostrils.

SHARJA, a seaport town of Oman, Arabia, capital of a province of the same name, on the Persian gulf, in lat. 25° 20' N., lon. 55° 36' E., 215 m. N. W. of Muscat; pop. about 25,000. It has a wall on the land side, but is open toward the harbor, which is a narrow creek running parallel with the coast, and deep enough for only small vessels. It has a large market place in the S. end, in the middle of which is the government treasury, a stone building strongly guarded. The shops are well built, and display Indian and Persian goods, and the manufactures of the place, principally red cloaks, carpets, curtains, arms, and filigree jewelry. A large part of the population are weavers, who occupy the N. quarter. Sharja is the principal port through which are imported the goods of Persia, and it is the chief place on the coast for the sale of cotton, wool, the metals, asses, and dromedaries. It has a large trade, and but for its inferior harbor it would be a place of much commercial importance. It is virtually independent.

SHARK, an extensive family of marine cartilaginous fishes, with the rays or skates and the chimæra or sea cat forming the order of plagiostomes or selachians, elevated under the latter name to a class by Agassiz. The sharks may be distinguished from the rays by their elongated fusiform body, branchial apertures on the sides of the neck, pectoral fins of the usual form and situation, and large, fleshy, and powerful tail, which is the principal organ of

locomotion; the nose is pointed and projects beyond the mouth, which is large and armed with formidable cutting teeth in several rows; the upper surface of the head often presents a pair of respiratory spiracles; the eyelids are distinct, with a free margin, and many have a nictitating membrane; the cartilaginous scapular arch is not attached to the spinal column, which contains more ossific matter than the other parts of the skeleton; the gills have their margins attached, the water escaping by five branchial openings (sometimes more); the skin is rough with osseous tubercles; the aortic bulb has several series of valves, and the shortness of the intestine is counterbalanced by an extended spiral valve. They are essentially carnivorous, and, as in the birds of prey, the females are larger and fiercer than the males; they swim with great ease and rapidity, playing around the fastest ships and steamers; they devour either living or dead animal matters, but, from the situation of the mouth on the under side of the head, are obliged to turn on the side or back to seize a large object. Many of the smaller species have received the names of dog and hound, with various canine epithets, from their habit of following their prey in packs. Sharks are higher than ordinary fishes in the phenomena of reproduction; there is with them true sexual union, and they are ovoviviparous, that is, the eggs are hatched in the oviducts, though they are often expelled before the embryo has quitted them; the egg presents in its early development many peculiarities of those of the higher vertebrates. In some the eggs are received into the villous oviduct, in which as in a uterus the young are developed; under these circumstances ova are observed in different stages of development, and frequently one in each oviduct. In others the egg is received in a horny, semi-transparent, oblong case, with long convoluted tendrils at each corner, deposited near the shore in the winter months, and moored by the tendrils; the case has an elongated fissure at each end for the entrance and exit of water; the young animal swims about for a time, deriving its nourishment from the attached yolk bag. The egg cases are often cast ashore by the waves, and are commonly known as sailors' purses. About 100 species of sharks are known, mostly in northern waters and the eastern hemisphere; some are almost cosmopolite, while others have a limited geographical distribution; the family contains the largest of the fishes, the great basking shark attaining a length of more than 30 ft.—In the family *scylliida*, generally called dog fishes to distinguish them from the sharks proper, spiracles are present; the snout is short and blunt; the gill openings are five, the last one over the base of the pectoral; two dorsals, far back and behind the ventrals; an anal present; caudal long, truncated at the end, with a notch on the under side; no caudal pit; a furrow at the corners of the mouth; teeth with a pointed median cusp, and

four or five small points on each side; the parts about the mouth and nose in some genera are divided into flaps and barbels, evidently organs of touch, necessary in their rapid passage along the bottom. They are oviparous, and the eggs resemble those of a skate. In the genus *scyllium* (Müll. and Henle) the spiracles are close behind the eyes, and the nostrils near the mouth and valved; dermal scales tricuspid. Most of the species are found around the southern coasts of Africa; they are among the smallest of the sharks, and live near the ground. There are two species on the English coast, the *S. catulus* (Cuv.) and *S. canicula* (Cuv.). The former is 2 or 3 ft. long, brownish gray above, with a few large blackish and white spots, and whitish below; the food consists of fish, mollusks, and crustaceans; it deposits about 20 eggs, according to Cuvier. The latter, the small spotted dog fish, about 2 ft. long, is more reddish, with more numerous and smaller spots; it is widely distributed, following ships and seizing whatever falls overboard; it eats chiefly fish, but has been known to attack fishermen and bathers; it lies in ambush in the mud or among weeds. Both these species are the pests of the fishing stations all along the coast, especially among the Orkney islands, robbing the lines at every opportunity, and not unfrequently caught themselves; the flesh is white, but dry and fibrous, and, though eaten by the fishermen, is rarely brought to market; in the Orkneys they are skinned, split, and dried; the skin is used by cabinet makers as a fine rasp, and the liver is valuable for its oil. Among the genera and species of N. E. Asia are many whose fins are used for soups by the Chinese. —Under the name of *squali* Cuvier comprehended all the other sharks, except the hammer-head and monk fish, of which he made distinct genera; Owen gives the name of *nectitantes* to a portion of the *squali*, chiefly *carchariadæ* and *galeidæ* (described below), the presence of a nictitating membrane to the eye being accompanied with a greater induration of the skeleton. In the family *carchariadæ* there are two dorsals and an anal, the first dorsal over the space between the pectorals and ventrals; there are no spiracles, and the last two gill openings are over the pectorals; nostrils generally small, pupil perpendicularly oval, and mouth boldly convex; the teeth are compressed, triangular, with an entire or serrated edge, arranged in a linear series like those of a saw, in several rows, of which the anterior only are erected for use; the tail has a short under lobe and a notch near the end of the upper; there is a pit above and below the base of the tail; the intestinal valve is longitudinally and not spirally rolled; skin comparatively smooth. The genus *carcharias* (Müll. and Henle) has been divided into various subgenera, but all have the nostrils midway between the mouth and end of the flattened snout, the labial cartilages very small, and the

yolk bag connected with a kind of uterine placenta in the smooth or villous oviduct. The white shark (*C. vulgaris*, Cuv.) attains a length of 30 to 35 ft., and a weight of more than 2,000 lbs.; the color is ashy brown above and whitish below; the head is large, the gape

White Shark (*Carcharias vulgaris*).

enormous, and the body stout; the teeth form such a perfect cutting apparatus, that the body of a man may be cleanly divided at a single bite; some of the jaws of this species (which are not the true jaw bones, however) are large enough, even when shrunk by drying, to slip over the body of a man; it has been seen near Calcutta to swallow a bullock's head and horns entire. This is the man-eater shark about which so many stories have been circulated, and human remains have been found in its stomach; it is gluttonous, savage, and bold; its ordinary food consists of large fish, seals, cuttle fishes, and decaying animal matters. It is found in almost all oceans, though most abundantly in tropical waters, and is a rapid and surface swimmer; it occasionally makes its appearance in the Mediterranean and on the British coasts. It is the terror of sailors, who always kill it when possible; as it follows ships to feed upon the garbage thrown overboard, and bites eagerly at any large bait dragging at the stern, it is not unfrequently caught, the precaution being taken to cut off the tail as soon as it is brought on board in order to prevent injury from its blows. The sense of hearing is very fine, if we can judge from the large size of the semicircular canals and vestibule of the ears. The young are born alive at different periods, until 20 or 30 are produced; they are 7 or 8 in. long at birth. This species meets with a formidable enemy in the sperm whale, and is often destroyed by it after a long and bloody combat; like all sharks, it is greatly infested with intestinal worms. The blue shark (*C. glaucus*, Cuv.) is a smaller species, rarely more than 8 ft. long; it is more slender and

elegantly formed, and the most beautiful in color of the sharks, being fine slate-blue above and white below; the skin is granulated and rough. It is distributed in most parts of the globe, and is very bold and voracious; its principal food consists of herring, shad, and other migratory fishes; it is a great pest to the British fishermen; when hooked, if it cannot divide the line, it rolls over and over so as to wind it around the body, sometimes beyond the power of extrication except by the knife; it also makes great havoc in the pilchard fishery, destroying the nets and devouring the fish. Like the white shark, this species is often attended by the pilot fish. (See PILOT FISH.) There are many stories of the affection of this species for its young, which are said to take refuge when alarmed in the stomach of the parent; there can be no doubt that small sharks are often found in the stomachs of the larger, but this is rather a proof of cannibalism than of parental affection. Of the American species of this genus may be mentioned the dusky shark (*C. obscurus*, Lesueur), attaining a length of 10 to 12 ft., dark brown above and dirty white below, occasionally found on the coast of the eastern and middle states; the small blue shark (*C. cæruleus*, Mitch.), 3 to 6 ft. long, slate-blue above and whitish below, found in the same waters; and Atwood's shark (*C. Atwoodi*, Storer), coming nearest the great white shark, attaining a length of 13 or 14 ft., and a weight of 1,500 lbs. The color of the last named is leaden gray above and white below; it has been caught off the coast of Massachusetts.

—In the *spinacidae*, piked dog fishes, spiracles are present; the anal fins are wanting, and the dorsals, two in number, are each preceded by a strong spine. The genus *acanthias* belongs to this family, and is described under DOG FISH.—In the family *galeidae*, topes or hounds, the fins, nostrils, gill openings, and mouth are as in the *carchariadæ*; there are very small spiracles; the teeth are alike in both jaws, with cutting edges and a cusp pointing obliquely outward; the upper lobe of the tail is much the longer and notched near the end; the scales small, three-ridged, with a median cusp. In the genus *galeus* (Cuv.) the pupil is round above and angular below; the teeth smooth on the inner edge, serrated on the outer, with the cusp smooth; the median teeth straight, jagged at the base on each side; no tail pits, and the intestinal valve spiral. The common tope or penny dog (*G. vulgaris*, Cuv.) attains a length of 6 ft.; the body is fusiform, slate-gray above and grayish white below; it is less rapacious than the blue shark, and is a pest to the fishermen in summer on the southern coasts of England; when hooked, if it cannot bite off the line, it rolls itself up in it; the young, to the number of 30 or more, are born in May and June; the liver is of some value for its oil. The genus *mustelus* (Artedi) of this family has been described under DOG FISH; in this the teeth are pavement-like as in the rays.

—In the family *lamnidæ* the gill openings are very large, all anterior to the pectorals; they have no nictitating membrane, and the spiracles are small, tail pits evident, caudal broadly forked and nearly crescentic, tail keeled on the sides, and the intestinal valve spiral. In the genus *lamna* (Cuv.) the snout is a three-sided pyramid with a short nasal flap, the spiracles far behind the eyes, and the mouth wide; the teeth are triangular, not serrated, with an acute toothlet at the base on each side, the surface resting on the jaw being deeply concave; there is a vacant space above and below instead of mesial teeth; skin comparatively smooth, and the scales very small. The porbeagle shark (*L. cornubica*, Cuv.), found on the northern coasts of Europe especially in autumn, attains a length of 9 ft.; it is uniform grayish black above and white below. They associate in small packs, from which and the porpoise-like form of the body the common name is derived; they feed chiefly on fishes and cephalopods; they are ovoviviparous. The mackerel shark (*L. [oxyrhina] punctata*, Mitch.) of North America is greenish on the back, lighter on the sides, and white below; the teeth are narrow, long and nail-like, calculated for holding rather than cutting prey; the head

Mackerel Shark (*Lamna punctata*).

and sides are punctured by a series of mucous pores. Like the English porbeagle, this species from its size and formidable teeth is the most dangerous of the common sharks, though it is not known to attack man unless in self-defence; it is common in summer on the New England coasts, and is a great pest to the mackerel and cod fishers; it may attain the length of 10 ft., but is usually not more than half this; it received its name from its following the shoals of mackerel on which it feeds; the liver is valuable for oil, a single fish often yielding six or seven gallons; though generally used by curriers only, when made carefully from fresh livers it is as good as whale oil to burn. The gray shark (*Odontaspis griseus*, Ag.) has the fore teeth simple, long, conical, with smooth edges and one or more basal toothlets; toward the corners the teeth are smaller and more incisorial; it attains a length of 4 to 7 ft., and is light bluish gray above, lighter on the sides, and white below; it is not uncommon in Long Island sound, and of late years in Massachusetts bay. In the genus *selachus* (Cuv.) the snout is short and blunt, and the gill openings almost meet under the throat; the teeth are very small and numerous, conical, without serrations, curving backward, and without toothlets and notches; scales

small, with radiating curved points, so that the skin feels rough; the eyes are very small. The great basking shark (*S. maximus*, Cuv.) is the largest of this class of fishes, attaining a length of 30 or 40 ft., and even over 50 ft., if the shark stranded at Stronsay in 1808, and

Great Basking Shark (*Selachus maximus*).

described as the sea serpent, belonged to this species. It descends in summer from the neighborhood of Greenland and Spitzbergen to the English channel and the middle United States. Notwithstanding its size and strength, it is the least ferocious of the sharks; it does not appear to feed on fishes, but on cuttle fishes, crustaceans, medusæ, and echini, and, according to Pennant, also on sea weeds. It is sluggish, and fond of reposing at the surface in the sun with the dorsal raised in the air, and hence called sun fish, sail fish, and basking shark; under these circumstances it is easily approached and harpooned; this is often done for the sake of the oil of the liver, which amounts to several barrels in a full-grown fish; from its speed and strength it is apt to pull a boat under water or overturn it; it has been known to drag a vessel of 70 tons against a fresh gale, and requires often 24 hours to fatigue and kill it. It is dark slate-colored above, and lighter below. The *S. elephas* (Lévesque) is probably the same species; it has been taken in the bay of Fundy 40 ft. long; on the New England coast it is called the bone shark by fishermen.—In the family *alopeciidae* the snout is short and conical, the spiracles and nostrils very small, the gill openings small, the last one over the pectorals; mouth comparatively small, the teeth not serrated, triangular, sharp, and alike in both jaws; no tooth on the mesial line, and a crescentic fold of skin behind the upper teeth; the second dorsal

Sea Fox (*Alopias vulpes*).

opposite the anal and very small; pectorals large and triangular; upper lobe of tail as long as the body, with a pit at the root; scales small and three-pronged, and intestinal valve spiral. It contains the single genus *alopias* (Raf.), and the single species *A. vulpes* (Raf.),

the sea fox, swingle-tail, or thresher shark; it attains a length of 15 ft., but is generally much smaller than this; the body is fusiform, bluish lead-colored above, white below, with light blue blotches on the outer edge of the abdomen. It attacks its prey and enemies and defends itself by blows of the tail; the food consists principally of herring, mackerel, and other surface and shoal fish. It is found in the European seas from the Mediterranean to the coast of England, and also on the American side from the British provinces to the middle states; it has been known to attack fishing boats in the bay of Fundy.—In the family *cestraciontidae* the nostrils are slit to within the mouth, which is at the fore end of the snout; the spiracles are rather behind the eyes; the gill openings small, the last one above the pectorals; a spine forming the front of each dorsal; tail short and wide, strongly notched below; teeth pavement-like, in rounded oblique scrolls; the body short and stout, head large, and eyes prominent. The genus *cestracion* (Cuv.) furnishes the only living representative of a family numerous in the secondary geological epoch; the *C. Phillipsii* (Cuv.) is 2 or 3 ft. long, brownish above and whitish below; it inhabits the Pacific from Australia to Japan; it is called nurse in Australia, and cat or kitten shark in China; the young are often seen in Canton insect boxes.—In the family *scymnidae* the dorsals are without spines, and there is no anal nor nictitating membrane; the upper teeth are pointed, the lower broader and cutting and not denticulated; no tail pits; intestinal valve spiral. In the genus *scymnus* (Cuv.) the spiracles are far behind the eyes, the gill openings small, the body short and thick, and the lobes of the tail not very unequal. The Greenland shark (*S. borealis*, Flem.) attains a length of about 14 ft., and is ashy gray; it inhabits the arctic seas, sometimes visiting the northern shores of Europe and America. It attacks whales fiercely, and scoops out at every bite a piece as large as a man's head, the mouth being 20 to 24 in. wide. According to Scoresby, they generally attend the cutting up of whales, helping themselves freely to blubber; the men often fall into the water among them, but are not attacked; they are so tenacious of life, and so insensible to wounds, that they will return to their prey after receiving lance stabs which would kill any other shark; the muscles, especially those of the jaws, retain their irritability for several hours after death; the heart is said to be very small, and its pulsations only six or eight in a minute, which would explain their tenacity of life and the difficulty of reaching any vital organ. They also eat small fishes and crustaceans. They are liable to the attacks of a parasitic crustacean (*Lernæa elongata*, Grant), 2 or 3 in. long, which fixes itself so often to the cornea of the eyes, that it was formerly supposed to be a natural appendage; this sometimes makes them apparently blind.

The nurse or sleeper shark (*S. brevipinna*, De Kay; *somniosus*, Lesueur) attains a length of 8 ft.; the color is leaden gray, darkest on the back, with a black lateral line; the fins are so small that it must be rather slow in its movements, and it is generally regarded as a ground shark; the skin is rough and prickly; a few specimens have been caught on the coast of Massachusetts.—In the family *squatinida*, the only genus, *squatina*, has been treated under the title ANGEL FISH.—In the family *zyganida* there is a nictitating membrane, no spiracles, and two spineless dorsals; the head is flat, with the orbits extended laterally in a most extraordinary manner, flexible and doubled on themselves in the fetus, but standing out at right angles and to a greater distance as age advances; on the end of these lateral processes are the large eyes. This strange form of head is found in no other vertebrate, and only in some dipterous insects (*diopsis*, &c.), and in many decapod crustaceans whose eyes are at the end of long pedicels. The snout is truncated, so that the head resembles a double hammer; the nostrils are on the front border, and have a small nasal flap; the teeth are alike above and below, compressed pyramids, sometimes with a serrated external basal ridge, and a mesial tooth in both jaws; tail pits distinct, and oviduct villous. Such are the characters of the only genus, *zygæna* (Cuv.) or *sphyra* (Van der Hoeven), of which the best known species is the hammer-headed shark (*Z. [S.] malleus*, Cuv.); it attains a length of 12 ft. or more, and is grayish above with head nearly black, and whitish below; the iris is yellow;

Hammer-headed Shark (*Zygæna malleus*).

the first dorsal is high, triangular, falcate, and toward the upper part of the back, the second smaller and near the tail. It is found in the Mediterranean and in the warm seas of most parts of the globe, especially of the East Indies, and generally in deep water. It is so ferocious

as to attack persons bathing, and is very voracious, feeding chiefly on rays and flat fishes; great numbers of them are sometimes seen together; the flesh is leathery and unfit to eat, but the liver yields considerable oil; a female opened at Penang was found to contain over 35 living young. The common species of America, between Massachusetts and Brazil, once considered the *Z. malleus*, has been described by Dr. Storer ("Proceedings of the Boston Society of Natural History," vol. iii., 1848) as the *Z. arcuata*; it attains a length of 11 or 12 ft., and is much dreaded by fishermen.—Large sharks abounded in former geological epochs, especially during the secondary and primary periods. In some of the tertiary formations, as at Malta, teeth of sharks have been found 7 in. long and $4\frac{1}{2}$ in. wide at the base.—The principal shark fisheries are on the N. and N. W. coasts of Iceland, in Norway, and on the arctic shores of Russia W. of the White sea, where they are pursued chiefly for the oil, and on the W. coast of Hindostan in the vicinity of Bombay, where they are pursued chiefly for the fins. These are sent to China, the annual exports from Bombay amounting to £15,000 or £20,000. The fins are also collected in the Indian archipelago.

SHARON, a borough of Mercer co., Pennsylvania, on the Shenango river, here spanned by two iron bridges, and on the Erie and Pittsburgh railroad, 60 m. N. N. W. of the latter and 64 m. S. S. W. of the former city; pop. in 1870, 4,221. The Mahoning division of the Atlantic and Great Western railroad affords a direct route to Cleveland and the west. There are large coal fields in the vicinity. Iron manufacturing is the chief business, the borough containing two large rolling mills with nail factories of more than 40 machines each, two extensive foundries and machine shops, and about half a dozen blast furnaces. There are two large planing mills, several smaller manufactories, two national banks, a savings bank, and a private bank, four hotels, three large brick school houses, a masonic hall, three weekly newspapers, and nine churches.

SHARON SPRINGS, a village of Schoharie co., New York, on a branch of the Albany and Susquehanna railroad, 45 m. W. by N. of Albany; pop. in 1870, 520. It is in a narrow valley surrounded by high hills, and is a favorite summer resort. It is chiefly noted for its mineral springs, of which there are four, chalybeate, magnesia, white sulphur, and blue sulphur. These, together with a spring of pure water, are near each other and near the base of a wooded bluff W. of the village, and flow into a small stream below. The village contains several hotels, and is visited by more than 10,000 persons annually.

SHARP, Granville, an English philanthropist, born in Durham in 1734, died in London, July 6, 1813. He was the son of Dr. Thomas Sharp, archdeacon of Northumberland, author of several philological, antiquarian, and religious

works, and grandson of Dr. John Sharp, archbishop of York. He quitted the study of law for a place in the ordnance office, which he resigned at the commencement of the American war, from disapprobation of the course pursued by the government. In 1769 he befriended a negro slave named Somerset, who had been brought to England, and on falling ill had been turned into the streets by his master. When two years later the negro's master claimed him, and had him arrested and imprisoned, Sharp summoned them both before the lord mayor, who discharged the slave; but the master refusing to give him up, Sharp brought the case before the court of king's bench, the 12 judges of which, in May, 1772, decided that a slave could not be held in or transported from England. From this time Mr. Sharp devoted his powers to the overthrow of slavery and the slave trade. He wrote numerous pamphlets on the subject, and was chairman of the meeting held in London, May 22, 1787, which formed the "Association for the Abolition of Negro Slavery." He was one of the founders of the British colony of Sierra Leone, drew up a plan for its temporary government, and sent many negroes there at his own expense. He also opposed the impressment of seamen, and advocated parliamentary reform and the extension of privileges to Ireland. Besides pamphlets, he published "Representation of the Injustice and dangerous Tendency of Tolerating Slavery in England" (8vo, London, 1772); "Declaration of the People's Natural Right to a Share in the Legislature" (1774); "The Law of Retribution" (1776); "Remarks on the Uses of the Definitive Article in the Greek Testament" (1798); "Account of the Ancient Division of the English Nation into Hundreds and Tithings, and View of Frankpledge" (1784); and "Three Tracts on the Syntax and Pronunciation of the Hebrew Tongue" (1804). His biography was written by Prince Hoare (4to, London, 1810).

SHARP, James, a Scottish prelate, born in the castle of Banff in May, 1618, assassinated on Magus Muir, near St. Andrews, May 3, 1679. He was educated for the church in the university of Aberdeen, and was one of its students who in 1638 declared themselves against the "Solemn League and Covenant." In 1640 he was chosen professor of philosophy in St. Leonard's college, St. Andrews, and shortly after became minister of the parish of Crail. In 1656 he was chosen to plead for the Presbyterians before the protector; and in 1660, when Monk marched upon London, he was regularly accredited to that general as their representative, and was sent over to Charles II. at Breda to procure the establishment of presbytery. He was received very favorably by the king, and obtained the royal word "to protect and preserve the government of the church of Scotland, as it is settled by law, without violation." The next Scottish parliament however repealed all acts passed

since 1633, the church "settled by law" thus becoming the old Episcopal church; and it was asserted that Sharp was an accomplice in this scheme. While in London he had been elected professor of divinity in St. Mary's college, St. Andrews, and also appointed the king's chaplain for Scotland with a salary of £200. In December, 1661, he was consecrated archbishop of St. Andrews, an appointment which rendered him excessively odious. The wanton cruelty with which the Covenanters were persecuted was attributed to him, and it is certain that, after the rout at Pentland hills, when he had received the king's order to stop the executions, he kept it for some time private. A creature of Sharp's named Carmichael had made himself particularly obnoxious to the Presbyterians, and nine men formed a plan to waylay and murder him. While they were waiting for this person, the archbishop passed by with his daughter and a few attendants; shouting, "The Lord has delivered him into our hands," they dragged him from his coach and despatched him.

SHARP, John, an English prelate, grandfather of Granville Sharp, born in Bradford, Yorkshire, Feb. 16, 1644, died in Bath, Feb. 2, 1714. He entered Christ's college, Cambridge, in 1660, was ordained in 1667, was made archdeacon of Berkshire in 1672, prebendary of Norwich in 1675, rector of St. Bartholomew's, London, in 1676, of St. Giles-in-the-fields in 1677, and dean of Norwich in 1681. He was chaplain to Charles II., and attended as court chaplain at the coronation of James II. For a sermon in 1686 against the claim of the Roman church to be called "the only visible Catholic church," the king suspended him, but he was reinstated in 1687. In 1689 he was made dean of Canterbury, and in 1691 archbishop of York. His sermons have appeared in several editions (7 vols., 1729-'35; 5 vols., 1829).—His son **THOMAS** (1693-1758), archdeacon of Northumberland, wrote his life (edited by Dr. Newcome, 2 vols., 1825), and published works against Hutchinsonianism, on "The Rubric and Canons of the Church of England," "Antiquity of the Hebrew Tongue and Character," &c. (collected, 5 vols. 8vo, 1763).

SHARPE, a N. E. county of Arkansas, bordering on Missouri, and intersected by Spring and Strawberry rivers, tributaries of Black river; area, about 600 sq. m.; pop. in 1870, 5,400, of whom 114 were colored. The surface is a plateau, divided into a series of ridges by numerous clear streams, with much good soil. Iron, lead, and zinc occur, and the last is mined. The chief productions in 1870 were 13,443 bushels of wheat, 200,090 of Indian corn, 13,447 of oats, 56,600 lbs. of butter, and 1,046 bales of cotton. There were 1,704 horses, 2,004 milch cows, 3,376 other cattle, 4,837 sheep, and 9,581 swine. Capital, Evening Shade.

SHASTA, a N. county of California, bounded W. by the Coast mountains, and intersected by the Sacramento river; area, 4,500 sq. m.;

pop. in 1870, 4,173, of whom 574 were Chinese. The surface is greatly diversified. Lassen's peak is 10,557 ft. high. The climate of the valleys is warm in summer, but mild and equable during the rest of the year, and many of them have a fertile soil. The N. and W. portions are covered with forests of conifers, while the E. part abounds in hot and boiling springs. The county contains gold, silver, and copper. It is traversed by the Oregon division of the Central Pacific railroad. The chief productions in 1870 were 29,569 bushels of wheat, 54,636 of barley, 9,748 of potatoes, 19,287 gallons of wine, 15,820 lbs. of wool, 30,150 of butter, and 5,034 tons of hay. There were 1,473 horses, 1,207 milch cows, 2,545 other cattle, 3,520 sheep, and 11,155 swine; 2 flour mills, 7 saw mills, and 3 quartz mills. Capital, Shasta.

SHASTA, Mount. See GLACIER, ROCKY MOUNTAINS, and SISKIYOU.

SHASTRA, or Shaster. See VEDA.

SHAT-EL-ARAB. See EUPHRATES.

SHATTUCK, Aaron D. See supplement.

SHAW, Henry W. See supplement.

SHAW, Lemuel, an American jurist, born in Barnstable, Mass., Jan. 9, 1781, died in Boston, March 30, 1861. He graduated at Harvard college in 1800, became a teacher and journalist, was admitted to the bar in September, 1804, and was a representative to the state legislature from 1811 to 1815, and again in 1819. In 1820 he was a member of the convention for revising the constitution of the state. In 1821 and 1822 he was a member of the senate, and again in 1828 and 1829. The charter of the city of Boston was drafted by him. He was appointed chief justice Aug. 23, 1830, and resigned Aug. 31, 1860. His reported decisions are found in the last 16 volumes of Pickering's reports, and in those of Metcalf, Cushing, and Gray; in all, upward of 50 volumes. He received the honorary degree of LL. D. from Harvard university in 1831, and from Brown university in 1850. He was a member of the corporation of Harvard college for 27 years.

SHAWANO, a N. E. county of Wisconsin, intersected by the Oconto, Wolf, Embarras, and Red rivers; area, about 1,500 sq. m.; pop. in 1870, 3,166. The surface is generally level and the soil fertile. Lake Shawano is in the central part, and fine streams of water abound. The chief productions in 1870 were 27,272 bushels of wheat, 3,144 of rye, 7,996 of Indian corn, 27,631 of oats, 20,273 of potatoes, and 1,964 lbs. of wool. Capital, Shawano.

SHAWL, a garment worn upon the shoulders or about the waist, and formed of wool, silk, hair, or cotton. The following are the principal varieties of shawls: those of Cashmere, woven in India or imitated in Europe, with the designs either embroidered upon the fabric, or by the more costly method worked into the web in the process of weaving, thus making both sides alike; crape shawls, made of silk in imitation of the Chinese fabrics; gren-

adines, made of silk of a peculiar twist; chenilles, of silk, often combined with cotton; chiné, made with a warp printed before weaving; barege, of wool, in imitation of shawls made by the peasantry at Baréges in the Pyrenees; woollen shawls of various kinds; and tartan plaids, made for centuries in Scotland. A description of the colors of tartans worn by the different clans in 1570 is extant. Their use was prohibited by act of parliament from 1747 to 1782; and they became fashionable from about 1828, and have so continued to some extent. The printing of shawl figures is done with blocks as in calico printing, and with the same elaborateness, as many as 100 blocks and 1,600 printings or applications being sometimes necessary for the production of a single pattern. The manufacture of Cashmere shawls was introduced from India in 1784 at Norwich, England, with the imported Thibet wool, and afterward with Piedmont silk warp and fine worsted shoot, the designs being worked in by hand. In 1805 the shawls were there first completed entirely upon the loom. About the same time the manufacture was introduced in Paisley and Edinburgh, and is still continued at the former place of the Indian pattern with real Cashmere wool. In Paris the manufacture was begun in 1802, and led Jacquard to the invention of his loom. In England the principal shawl-printing establishment is at Crayford in Kent. In the United States, the business was begun at Lowell, Mass., but has since been established at several other places, and has been very greatly extended. (For statistics on the India shawl trade and other information, see CASHMERE.)

SHAWNEE, a N. E. county of Kansas, intersected by the Kansas river; area, 546 sq. m.; pop. in 1870, 13,121. It is traversed by the Atchison, Topeka, and Santa Fé, and the Kansas Pacific railroads. The surface is undulating or level, and the soil fertile. Coal and limestone abound. The chief productions in 1870 were 46,726 bushels of wheat, 602,475 of Indian corn, 60,853 of oats, 84,656 of potatoes, 238,005 lbs. of butter, and 19,122 tons of hay. There were 3,461 horses, 3,562 milch cows, 6,556 other cattle, 1,832 sheep, and 4,904 swine; 1 bookbindery, 2 flour mills, 2 saw mills, 3 manufactories of carriages and wagons, 4 of furniture, 1 of machinery, and 7 of tin, copper, and sheet-iron ware. Capital, Topeka, which is also the capital of the state.

SHAWNEES, an erratic tribe of the Algonquin family. A tradition of recent origin makes them primarily one with the Kickapoo nation; but they moved eastward, and a part are said to have remained in 1648 along the Fox river, while the main body, met south of Lake Erie by the Iroquois, were driven to the banks of the Cumberland. Some passed thence into Carolina, and others into Florida. Toward the close of the 17th century one band went north, and was among the tribes occupying Pennsylvania when it was granted to Penn,

who made treaties with them in 1682 and 1701. In 1693 and in 1722 they made treaties at Albany with the Iroquois of New York and Virginia. The portion in Florida maintained friendly relations with the Spaniards for a time, but finally joined the English in Carolina, and were known as Savannahs or Yamassees. After their war they retired to the Creeks, and finally joined the northern Shawnees. The Iroquois claimed sovereignty over the Shawnees, and drove them to the west. In 1731, rejecting the English missionaries, they negotiated with the French, and gave early aid to them in the final struggle; but in 1758 they were won over by Post, and by the appearance of Gen. Forbes. After the fall of Canada they joined Pontiac, and were active in hostilities till subdued by Bouquet. In 1774, enraged at Cresap's attack, they roused most of the western tribes, and in October defeated the Virginians at Pleasant Point, but made peace the next year. In 1779 Col. Bowman marched against the Shawnee towns, but was twice defeated. They joined in the peace of 1786, but, under English influence, took part in the Miami war, in the campaigns against Harmer and St. Clair, till they were finally reduced by Gen. Wayne, and they submitted under the treaty of Greenville (1795). The main party were at this time on the Scioto; but some had crossed into Missouri, where the Spaniards gave them land. Another band moved south. In the war of 1812 some of the bands were won by the English. Urged by Tecumseh and his brother the prophet, they endeavored to unite all the Indians of the west against the Americans, but those in Ohio remained faithful. The Missouri band ceded their lands to the government in 1825, and the Ohio band in 1831. In 1854 the band of Shawnees proper, in that part of the Indian territory now included in Kansas, numbered 900 on a reservation of 1,600,000 acres; but by treaty the tribal relation was ended and the lands were divided in severalty. Besides these, there were in 1872 90 in the Quapaw agency, and 663 in the Sac and Fox agency. The Methodists, Baptists, and Friends have all labored among this tribe.

SHAYS, Daniel, leader in 1786-'7 of the rebellion in Massachusetts which bears his name, born in Hopkinton, Mass., in 1747, died in Sparta, N. Y., Sept. 29, 1825. He served as a sergeant at Bunker Hill, and became a captain during the revolution. Although not prominent in the first movements of the rebellion, Shays was chosen commander. The insurgents complained that the governor's salary was too high, the senate aristocratic, the lawyers extortionate, and taxes too burdensome to bear; and they demanded an issue of paper money and the removal of the legislature (general court) from Boston. An effort was made to allay the discontent by the passage of an act to diminish costs in the collection of debts and allow certain back taxes and debts to be paid

in produce, but the mob was not satisfied. Bodies of armed men interrupted the sessions of the courts in several counties, and in December, 1786, Shays appeared with a large force at Worcester and Springfield, and prevented the holding of the courts at those places. In January following, at the head of nearly 2,000 men, he marched to capture the arsenal at Springfield, but was opposed by the militia under Gen. Shepherd, and the insurgents were fired upon and fled, leaving three killed and one wounded on the field. Next day they were pursued by a large force under Gen. Lincoln, and at Petersham 150 were taken prisoners, the remainder dispersed, and the leaders made their escape into New Hampshire. A free pardon offered to all who would lay down their arms was generally accepted; 14 were tried and sentenced to death, but were pardoned. Shays sought safety for about a year in Vermont, and at his petition was afterward pardoned, and settled at Sparta, N. Y.

SHEA, John D. Gilmary, an American author, born in New York, July 22, 1824. He was educated at the grammar school of Columbia college, and was admitted to the bar, but devoted himself to literature. He is chiefly known for works on American history, the most important of which are: "The Discovery and Exploration of the Mississippi Valley" (New York, 1853); "History of the Catholic Missions among the Indian Tribes of the United States" (1854; German translation, Würzburg, 1856); "The Fallen Brave" (1861); "Early Voyages up and down the Mississippi" (Albany, 1862); "Novum Belgium, an Account of New Netherland in 1643-'4" (New York, 1862); "The Operations of the French Fleet under Count de Grasse" (1864); "The Lincoln Memorial" (1865); and a translation of Charlevoix's "History and General Description of New France," with extensive notes (6 vols. 8vo, 1866-'72). He is also the joint author and the translator of De Courcy's "Catholic Church in the United States" (1856). He has edited the Cramoisy series of "Relations" and documents bearing on the early history of the French American colonies (24 vols., 1857-'68); "Washington's Private Diary" (1861); Colden's "History of the Five Indian Nations," edition of 1727 (1866); Alsop's "Maryland" (1869); and a series of grammars and dictionaries of the Indian languages (15 vols. 8vo, 1860-'74). He has also published "Bibliography of American Catholic Bibles and Testaments" (1859), corrected several of the very erroneous Catholic Bibles, and revised by the Vulgate Chaloner's original Bible of 1750 (1871; 2d ed., with a translation of Allioli's commentary, 1875); and has issued several prayer books, school histories, and translations. He edited for eight years the "Historical Magazine," and has contributed largely to periodicals and publications of historical societies.

SHEARWATER, a web-footed bird of the petrel family, and genus *puffinus* (Briss.). The

bill is about as long as the head, slender, compressed near the end and grooved obliquely on the sides, with strong, curved, and acute tip; nostrils basal, with two distinct tubes, side by side; wings very long and pointed, the first quill longest; tail short and rounded; tarsi as long as middle toe and compressed; toes long and united by a full web; in some there is a straight claw in place of a hind toe. They are moderate-sized, found in both hemispheres, and are met with at sea, often many hundred miles from land, even in the most tempestuous weather, skimming and running over the waves in search of food; they are light and graceful swimmers, good divers, and pat the surface of the water with their feet like the petrels; they are rapid fliers, and can keep on the wing all day, resting on the ocean if need be at night; they breed in company, in burrows made by themselves or small mammals; they lay only one egg, and the young are covered with long down.—The greater shearwater (*P. major*, Faber) is about 20 in. long and 45 in. in alar extent; the upper plumage is brownish ash, the

Greater Shearwater (*Puffinus major*).

lower grayish white; lower back and upper tail coverts dark brown; primaries and tail brownish black, the feathers of the wings with white on the inner webs; bill yellowish green, with dark tip; tarsi and feet yellow. This species is found on the European side of the Atlantic, and ranges on the American coast from the gulf of St. Lawrence to Florida. It mingles with the fulmars, and on being approached ejects from the nostrils an oily substance; on land, where it goes only to breed, it walks as well as a duck. The food consists of fishes, crustaceans, algae, and other marine products, and floating animal substances. The Manx shearwater (*P. Anglorum*, Ray) is 15 in. long and 32 in. in alar extent; the upper plumage is black, the under white, bill brownish black, legs and feet dull orange. It is abundant on the Orkney and other northern islands, and on the American coast from New Jersey to Labrador; it breeds in rabbit burrows in the Orkneys between March and August, and all the rest of the year is at sea; the young are fat, and the natives salt and eat

them.—Some writers give the name shearwater to the genus *rhynchops*. (See SKIMMER.)

SHEATHBILL (*chionis*, Forst.), a genus placed by Gray among the gallinaceous birds, but by Latham, Cuvier, and Van der Hoeven among the waders. The bill is short, strong, compressed toward the tip, the culmen curved, and the base covered with a movable horny substance, more or less concealing the nostrils; base of bill and cheeks covered with a warty naked skin; wings moderate, the second quill the longest, and the bend with a blunt knob; tail moderate and even; tarsi short, strong, covered with small rough scales; toes moderately strong, with transverse scales, the outer united to the middle one by a membrane at the base, and the hind one small, elevated, and on one side; claws short and blunt. The white sheathbill (*C. alba*, Forst.) is from 15 to 18 in. long; the plumage is pure white, the bill and knob of wing black; the legs bare a little above the joint, and reddish. It is found in New Zealand, Australia, and the islands of the Antarctic ocean, where it frequents the shores in flocks, searching for food, which consists of mollusks, sea weeds, and animal remains; numbers have sometimes been seen by southern voyagers at a great distance from land, resting on icebergs and feeding on refuse matters. The flight is like that of the pigeon; the flesh is said to be excellent. With the general appearance of a gallinaceous bird, the sheathbill has the habits of a wader.

SHEBA, or **Saba**, in ancient geography, the capital city of the Sabæans in Arabia Felix. Its exact site is unknown. The territory of the Sabæans lay near the Red sea, and ran up to the borders of the desert. They were, partly at least, Semitic tribes, monarchically governed, the first child born in a certain number of noble families after the accession of a monarch being the presumptive heir to the throne. They held for centuries the keys of the commerce between Europe and India, and Egypt and Syria, produced and sold frankincense and aromatics, and were reputed for their opulence and luxury among the Hebrews, Greeks, and Romans. A queen of Sheba was attracted by the fame of Solomon to visit Jerusalem (1 Kings x. 1-13). The Sabæans were ultimately subjected by the Himyarites. The traveller Niebuhr was the first to assert that the country could never have produced gold, and that some of its finest spices and perfumes were probably imported.—The name of Saba was given by classical writers to other cities both on the Arabian and Ethiopian sides of the Red sea. In the Hebrew Scriptures, in contradistinction from the Arabian Sheba, the region of the Ethiopian Sabæans is called Seba.

SHEBOYGAN, an E. county of Wisconsin, bordering on Lake Michigan, drained by Sheboygan river and its tributaries, and by tributaries of Milwaukee river; area, 500 sq. m.; pop. in 1870, 31,749. It is traversed by several railroads. The chief productions in 1870 were

604,531 bushels of wheat, 93,165 of rye, 75,198 of Indian corn, 418,083 of oats, 56,767 of barley, 21,810 of buckwheat, 138,786 of potatoes, 96,984 of peas and beans, 39,351 tons of hay, 127,241 lbs. of wool, 710,010 of butter, 120,005 of cheese, 31,954 of hops, and 25,522 of maple sugar. There were 6,403 horses, 10,487 milch cows, 11,322 other cattle, 31,734 sheep, and 8,977 swine; 7 manufactories of agricultural implements, 9 of carriages and wagons, 8 of cheese, 41 of cooperage, 9 of furniture, 4 of iron castings, 1 of railroad cars, 3 of wood work, 2 of woollen goods, 10 breweries, 7 brick yards, 5 tanneries, 12 flour mills, and 12 saw mills. Capital, Sheboygan.

SHEBOYGAN, a city and the capital of Sheboygan co., Wisconsin, on Lake Michigan, at the mouth of Sheboygan river, 52 m. N. of Milwaukee; pop. in 1870, 5,310; in 1875, 6,828. It has a good harbor, and ships annually to Buffalo about 500,000 bushels of wheat. It is on the Milwaukee, Lake Shore, and Western railroad, and is the E. terminus of the Sheboygan and Fond du Lac railroad. It contains two extensive chair factories, besides 52 other manufacturing establishments of various kinds. It has one national and one private bank, a high school and other public schools, three weekly newspapers (one German), and ten churches. It was first settled in 1836.

SHECHEM, a city of ancient Palestine, called also Sichem, Sychem, and Sychar, 30 m. N. of Jerusalem, on or near the site of the modern Nablus. The allusions to it in the Old Testament are numerous. Abraham worshipped under an oak near Shechem on his first visit to the land of promise; Jacob encamped near it, and the defilement of his daughter Dinah by the son of the local chieftain led to the capture of the place and slaughter of all the male inhabitants by his sons Simeon and Levi. After the conquest of Palestine Shechem was assigned to the Levites and became a city of refuge; the bones of Joseph were buried here in the field purchased by his father from Hamor; hither Joshua assembled the tribes to hear his last counsels. After the death of Gideon, his illegitimate son Abimelech induced the Shechemites to revolt and make him their king. Three years later they expelled him, and he destroyed the city; but it was soon rebuilt, and the reign of Rehoboam was here inaugurated. Here the ten tribes renounced their allegiance to the house of David, and chose for their king Jeroboam, who made the city his capital. After the captivity Shechem became the chief seat of Samaritan worship, and remained such until its destruction by Vespasian, after which it was rebuilt and called Neapolis. (See **NABLUS**.)

SHEDD, William Greenough Thayer, an American clergyman, born in Acton, Mass., June 21, 1820. He graduated at the university of Vermont in 1839, and at Andover theological seminary in 1843, and was ordained pastor of the Congregational church in Brandon, Vt., in

1844. In 1845 he became professor of English literature in the university of Vermont, in 1852 of homiletics in Auburn theological seminary, and in 1854 of church history in the Andover theological seminary. In 1862 he was installed as associate pastor of the Brick church (Presbyterian) in New York, resigned in 1863, and became professor of Biblical literature in the Union theological seminary, and in 1874 of doctrinal theology. He has published "Outlines of a System of Rhetoric," from the German of F. Theremin (12mo, New York, 1850); "Lectures upon the Philosophy of History" (Andover, 1856); "Discourses and Essays" (Andover, 1856); "A Manual of Church History," from the German of H. E. F. Guericke (8vo, Andover and Edinburgh, 1857); "A History of the Christian Doctrine" (2 vols., New York, 1863); "Homiletics and Pastoral Theology" (1867); and "Sermons to the Natural Man" (1871). Prof. Shedd has also edited the works of Coleridge (7 vols. 12mo, New York, 1853), "The Confessions of Augustine," with an introductory essay (Andover, 1860), and the Gospel of Mark in vol. ii. of the translation of Lange's commentary; and has contributed an introduction to Asbury's translation of Ackermann's work on the Christian element in Plato, and to the American edition of McCosh's "Intuitions of the Mind."

SHEE, Sir Martin Archer, an English painter, born in Dublin, Dec. 23, 1770, died in Brighton, Aug. 19, 1850. He studied painting in Dublin under F. R. West, and at the age of 16 was a successful portrait painter. In 1788 he went to London, and became a pupil in the royal academy, to the exhibition of which he contributed his first pictures in 1789. In 1798 he was chosen an associate, and in 1800 a member of the royal academy, and in 1830 he became president and was knighted. Shortly before his death he was granted a pension of £200, with succession to his daughters. He published two parts of a poem entitled "Rhymes on Art" (1805, 1809); "The Commemoration of Sir Joshua Reynolds, and other Poems" (1814); "Alasco," a tragedy (1824); "Oldcourt," a novel (1829); and "Outline of a Plan for the National Encouragement of Historical Painting" (1837). His life has been written by his son (2 vols., London, 1860).

SHEEAHS. See **SHIAHS**.

SHEEP, a hollow-horned, wool-bearing, ruminating animal, of the genus *ovis* (Linn.). The genus is characterized by horns common to both sexes in the wild state (though sometimes wanting in the females), large, angular, transversely wrinkled, yellowish brown, curved backward, laterally, and spirally, the tip coming forward, and with a porous bony axis; arched forehead, distinct lachrymal sinus, and hairy muzzle; absence of inguinal pores and of beard under the chin; two mammae, small ears, slender legs, and short tail; and hair of two kinds, one woolly, the other exterior, closer, and harsher. In a domesticated state the wool

predominates over the hair, the horns vary or disappear, the ears and tail lengthen, and other characters undergo great modifications. Though the sheep is externally sufficiently distinct from the goat (*capra*) in general appearance, covering, and horns, the generic differences are not so evident when the whole series of these animals is examined; they run into each other so closely that some naturalists have included them in a single genus. The sheep differs from the goat chiefly in the form of the horns, absence of beard, and presence of an opening on the anterior part of each foot between the hoofs, whence issues a sebaceous secretion; the males are not so odorous as in the goat. Sheep are gregarious, timid, defenceless, and more dependent on man's care than the goat; they inhabit the mountainous regions of temperate climates, and climb rocks and precipices with facility and speed. Some naturalists count four or five distinct species, one of which is found native in each continent; there are few parts of the globe except the polar regions where some breed of the sheep is not found; they thrive remarkably in temperate Australia, producing fine fleeces; in the tropics the wool degenerates into hair. In the skeleton the parietal bone is in the form of a flattened band, encircling the cranium between the orbital wings of the sphenoid, and is narrower than in the goats; frontals large and broad; squamous portion of temporals small, and the tympanic bullæ large, terminating anteriorly by a sharp styloid process; nasals long and convex, forming a single V-shaped bone; ascending portion of intermaxillaries at a very oblique angle, and the incisive openings very large and elongated; infraorbital opening on a line with the second premaxillary; lachrymals large, articulating with the nasals; malar bones broad, thick, and much prolonged on the cheek; palate bones largely developed, deeply notched posteriorly. According to Cuvier there are 46 vertebrae, of which 7 are cervical, 13 dorsal, 6 lumbar, 4 sacral, and 16 caudal. The intestinal canal is very long and simple, the small intestines very much convoluted, and the large of nearly the same size, the whole 28 times as long as the body; the stomach compound; hepatic duct enormously large; brain elongated, narrowed in front; organ of smell highly developed. (For other anatomical details, see RUMINANTIA.) The dental formula is: incisors $\frac{2}{2}$, canines none, molars $\frac{3}{3}$; they begin to change their teeth in the first year, and have all their permanent teeth at three years, except the outer two incisors; the last, according to Owen, in the lower jaw, represent canines, as shown by the analogy of the camels, their lateness of development and peculiarity of form; this holds true in all the *cavicornia* or hollow-horned ruminants.—Sheep formed the principal wealth of the Hebrew patriarchs, and the term *pecus* (cattle) of the Latins, whence was derived *pecunia*, wealth, was applied especially to them;

they came into N. and W. Europe long after the goat, and there is no evidence of their crossing the Rhine or upper Danube until about the time of the fall of the Roman empire, though they then existed in S. Europe. In old times they were bred chiefly for their skins and milk, the last being abundant, agreeable, and highly nutritious. Now they are valued most for their wool, flesh, and fat; their flocks well managed carry fertility wherever they go, the droppings being richer than any other manure except that of fowls; they are even employed as beasts of burden in the mountains of India; the skins with the wool on are used in some countries for garments, and in the form of leather for gloves, book covers, and for various other purposes; the wool has the property of felting on account of the imbricated scaly surface of the fibres.—The Corsican musimon or moufflon (*O. musimon*, Pall.), placed by Bonaparte in the genus *capra* on account of the absence of interdigital glandular openings, and the type of the genus *caprovius* from its resemblance to a goat, grows as large as a small fallow deer, and has very large horns; it inhabits the mountains of Corsica, Sardinia, the southern part of Spain, European Turkey, and the eastern Mediterranean islands, where however it is comparatively little known. The head is long, with compressed muzzle, swollen forehead, and large, erect, and sharp ears; the horns of the male are long and triangular, comprising more than half a circle, their bases occupying almost all the forehead and separated only by a small space; they grow gradually smaller to the obtuse tip, with transverse wrinkles and raised rings; the body is large and muscular, the tail with 12 vertebrae, turned down and bare on the under side; the legs long and muscular, and the hoofs short; there is an appearance of a moderate dewlap. The general color is yellowish, with a chestnut tinge, deepest on the neck; head ash-gray; muzzle, space about eyes, interior of ears, abdomen, inside of thighs, edges of tail and end of legs, white; horns ochrey brown; the under wool is ashy or rusty white, and the hair is darker and thicker in winter; the females are without horns, or have very small ones. The average size is about 4 ft. in length and 32 in. in height; there is sometimes a tuft under the chin, and other marks also indicate it to be intermediate between sheep and goats. They are seen in flocks of 100 or more, headed by an old male; they breed with the domestic races, and have been themselves domesticated.—The Asiatic argali (*O. Ammon*, Cuv.), very similar to the moufflon in general form, is large and powerful, the male standing 3 ft. high at the shoulders and weighing 200 lbs.; the horns 4 ft. in their curve, with a weight of 30 lbs. The fur is short, fulvous gray in winter, with a ferruginous or buff dorsal stripe, and a light brown anal disk; it is more rufous in summer. It inhabits the highest mountain ranges of Asia, the Caucasus, and the plains of Siberia.

ria; its flesh is much esteemed, and in Russia the skins are still used as articles of dress; it is easily domesticated, and is generally believed to be the source of some of the eastern breeds

Asiatic Argali (*Ovis Ammon*).

of sheep; the females have small horns. The African argali or bearded sheep (*O. tragelaphus*, Cuv.), the aoudad and *ammotragus* of some authors, is another species intermediate between the sheep and goats, having the interdigital glands of the former, and the absence of lachrymal sinuses of the latter; it is one fifth larger than the European sheep, with a tail about 7 in. long, ending in a pencil of hairs; the horns are small in comparison with the size of the body, and rather smooth. The color is uniform reddish yellow, with dorsal stripe and anterior part of limbs brownish; under parts and inside of limbs whitish; the anterior parts of the neck, body, and legs are furnished with hair 6 to 12 in. long. It in-

Rocky Mountain Sheep (*Ovis montana*).

habits the mountains of N. Africa, from Abyssinia to Barbary, in small flocks; it is fierce, and bravely defends itself. America has also an argali, the Rocky mountain sheep (*O. mon-*

tana, Cuv.), called big-horn from the great size of the horns; it is found in flocks of 3 to 30, from the upper Missouri and the Yellowstone river to the Rocky mountains and the high grounds on their eastern slope, as far S. as the Rio Grande, E. to the Mauvais Terres of Nebraska, and W. to the coast ranges of Washington territory, Oregon, and California; it is said to range as far N. as lat. 68°, but is not found in the hilly regions near Hudson bay. None of the domestic breeds have been traced to this, though it would no doubt cross with them; the effect of all domestication is to improve the fleece, shortening the hair and increasing the wool.—The musimon of Corsica and the Asiatic argali, though differing somewhat in the skeletons from the domesticated races, have generally been considered as their most probable origins. The domestic sheep (*ovis aries*, Linn.), from whichever of the preceding it be derived, presents a great variety of breeds, only a few of the principal of which can be noticed here; several of them have received distinct specific names. Among the African sheep is the Fezzan breed, remarkable for the long legs, pendulous ears, arched forehead, and short, curled, and crispy fleece, like a mane on the neck and whorled on the shoulders; the usual colors are black and white. Nearly allied to this is the Persian sheep, with black head and neck, and the rest of the body white; it is very docile and affectionate. From the last or the Fezzan seem to have sprung the Morocco, Congo, Guinea, and Angola breeds; H. Smith figures a variety called the Zunu or goitred breed, having a high collar of fat behind the horns and a goitre-like fatty mass on the larynx. There are several breeds of large-tailed or fat-rumped sheep in S. Africa, extending over that continent and also to Asia; the Hottentot or broad-tailed breed is below the medium size, with short and soft fleece, and two large masses of fat on each side of the lower part of the tail, which are so esteemed as a delicacy that various contrivances are used to prevent them from dragging on the ground; the fat-rumped sheep of Tartary and temperate Asia (*O. steatopyga*) has a similar growth of fat upon the croup, and long and pendulous ears; the reason of this accumulation of fat, sometimes 70 to 80 lbs., has not been satisfactorily determined.—The most important breed of sheep as regards the texture of the wool is the merino (*O. Hispanica*), in modern times brought to the greatest perfection in Spain, though its originals probably formed the flocks of the patriarchs thousands of years ago, and have been the stock of all the fine-wooled sheep. Unlike the British breeds, they have wool on the forehead and cheeks; the horns are very large and heavy, and convoluted laterally; the wool is fine, long, soft, twisted in silky spiral ringlets, and naturally so oily that the fleece looks dingy and unclean from the dust and dirt adhering to the outside, but perfectly white underneath; the form is not so sym-

metrical as in many English breeds, and there is generally a loose skin hanging from the neck. They are kept in the milder regions in winter, and are transferred to the most fa-

Merino Sheep (*Ovis Hispanica*).

vorable localities for shearing and grazing; they are most hardy in the Pyrenees. They are brought every night to a sheltered level valley, but are never housed nor under cover; four shepherds and six large dogs are sufficient for 2,000 sheep; the dogs can easily master a wolf, alone protect the flock at night, and are fed only on bread and milk. Most of these sheep have the horns removed; the legs are white or reddish; the face is in some speckled, and in others white or reddish; they are sometimes black; they are excellent travellers; they have in a remarkable degree the mellow softness under the skin which Bakewell considers an indication of a disposition to fatten in any breed; they are extremely docile. The average fleece is 4 to 5 lbs.; several million pounds are annually exported from Spain. They readily form cross breeds, called demi-merinos, which have been brought to great perfection in France, whence, as well as from Spain, they have been imported into America. Other fine-wooled varieties of the merino are the Saxon, Silesian, and Flemish breeds, the last abundant in France and the Netherlands, and generally hornless, high on the legs, and mixed with the Barbary long-legged variety. The Astrakhan or Bokharan breed has a fine spirally twisted wool, and furnishes a great portion of the lamb skins so highly valued by furriers; it is generally a mixed black and white; in the very young each lock is divided into two small twisted curls. The Caucasian breed (*O. dolichura*) is very handsome, resembling some of the Spanish and English varieties; the males are horned, the wool of the adults coarse, and the tail, which consists of 20 vertebrae, is covered with a fine wool, which drags on the ground; they are generally white; by gentle pressure on the wool by linen coverings as the lamb grows, and by pouring warm water over it daily, it is made to lie in beautiful glossy ringlets, constituting a delicate fur much esteemed for lining robes and dressing

gowns; the black is most prized. The Mysore breed of India is without horns, with pendulous ears, short tail, and very fine wool, curled in small meshes and twisted like a corkscrew.—There is no country where more attention has been paid to the improvement of the breeds of sheep, both domestic and foreign, or where more success has been attained, than Great Britain; there are very valuable British breeds suited for the rich soil, luxuriant pastures, and mild climate of southern England, the thinner soil and rich grasses of the upland counties, and the alpine herbage and cold weather of the Scottish highlands; looking to a combination of advantages, some of the English breeds take the first rank for the small farmer. The Leicester or Dishley breed is the most esteemed of the long-wooled sheep of England, and is extensively reared on the rich and lower pasture lands. It may be known by the clean head without horns, lively eyes, straight, broad, and flat back, round body, small bones, thin pelt, disposition to make fat at an early age, and a fine-grained and well flavored flesh. It was once known as the Lincolnshire breed, noted for the quantity of the wool and the coarseness of the mutton; Mr. Bakewell effected the improvement in the breed, with great profit to himself and advantage to the wool-growing interest of his country; it has extended to the south of Scotland, and a few are kept by almost every small farmer for the wool; the fleece is abundant, the flesh excellent, and the habits docile and home-loving; a valuable breed has sprung from its mixture with the black-faced and Cheviot varieties. The black-faced or heath breed extends from the N. W. parts of Yorkshire to the highlands of Scotland, especially on the W. coast; it is active, hardy, almost goat-like in its climbing habits, with a compact shape and bright, wild-looking eyes; the horns of the male are very large and convoluted; the wool is long, coarse, and shaggy, and the face and slender legs always jet-black;

Leicester Sheep.

in some mixed breeds the face and legs are brownish spotted with black; the flesh is fine-grained and of excellent flavor, but the wool is comparatively unprofitable, the Cheviot, an-

other northern breed, being generally preferred as equally hardy and better fleeced. Many attempts have been made to improve it, and the Norfolk, Suffolk, and Dorset breeds are supposed to be derived from it. In the Cheviot the head is bare and clean, the face and legs white, the body long, bones small, and fleece of about 3 lbs. The Dorset is an old but handsome breed, with strong and well formed body, finely curved horns, and clear white fleece; they drop their lambs as early as September. The Southdown breed is dark-faced, without horns, with long small neck, very short and fine fleece of $2\frac{1}{2}$ to 3 lbs., and celebrated for the fine flavor of the mutton; it is in the greatest perfection in Sussex, on the chalky downs. Other British breeds without horns and with white face and legs are the Teeswater, Dartmoor, Hereford, and Romney Marsh; and with horns, the Exmoor and Spanish.—America has no indigenous domestic sheep. The first sheep were introduced into the United States at Jamestown, Va., from England in 1609, which in 40 years had increased to 3,000; they were introduced into New York and Massachusetts about 1625. Both Spanish and French merinos have been introduced, the former by David Humphreys, minister to the court of Madrid, in 1802, and the latter by Mr. Taintor, of Hartford, Conn., in 1846. They are hardy, yielding a large amount of fine wool for their size, the males 10 to 16 lbs. of washed wool, and the females 4 to 8, the former weighing from 140 to 175 lbs., the latter from 80 to 130. They thrive in summer on grass and clover, and in winter on hay, wheat bran, barley, oats, and root crops; in winter they require sheds for protection, free space, pure air, and water accessible. The best breeds are generally considered to be the Vermont Brewer and Atwood flocks; some regard the Saxon merinos as the best, and the French have less oil in their wool than the Spanish. The Leicester breed has a heavier fleece and carcass, but requires more food; as combining the advantages of wool and meat, this is the best breed for the farmer, and is excellently bred in New Jersey; the wool is long staple, and is used mostly for combing purposes, for delaines and similar cloths. The Southdowns are by many preferred to the merinos, as a third larger, hardier, and better mutton; they are very prolific, and the lambs are hardy; the wool is large in quantity and fair in quality. The Cotswold also is highly esteemed. As a general rule, the fine-wooled sheep, like the merino, Saxon, French, and Silesian, are not so profitable for the mutton as the coarse-wooled, like the Leicester, Southdown, and Cotswold; it seems impossible to combine in a single breed both these qualities in their greatest perfection. The northern and western states raise the best sheep for mutton, and the middle and southern for wool.—Sheep are remarkably affected by changes of external condition, as of climate, food, &c., and congenital varieties

thence arising may be easily perpetuated. In Massachusetts in 1791 a lamb was born with a longer body and shorter legs than the rest of the flock, with longer joints and crooked fore legs; as it could not leap over fences, it was determined to propagate its peculiarities, and from it arose the famous otter breed, now extinct; when both parents were of the otter breed, the lambs inherited the form.—Sheep are subject to many diseases, of which the most troublesome is the foot rot, from suppression of the secretion of the gland between the hoofs, and consequent inflammation, generally caused by standing on too wet ground; the best remedy is to pare the diseased hoof thoroughly and apply a solution of blue vitriol (sulphate of copper), 1 lb. to a quart of water; the animal should also be kept in a dry place. They suffer from insects, especially a bot fly (*astrus ovis*), the larvæ of which get from the lips and nostrils into the frontal and maxillary cavities, causing fatal disease; the wild sheep of elevated regions suffer least from these. They are infested with a species of tick, which may be killed after shearing by a weak solution of tobacco and water, or a preparation of oil, lampblack, and umber. Sheep are more choice in their food than goats, and yet will thrive where most other animals would starve; they prefer alpine and aromatic plants, and will soon clear a field of weeds, briars, and bushes, and by their droppings prepare it for the plough. They cannot be economically kept amid a dense population, as they would occupy too much land; and they are not profitable to pasture with cows, as they bite the grass too close for the latter to thrive upon.—For full information on the statistics and profits of sheep husbandry, see the agricultural reports of the department of the interior at Washington, and the publications of the various state agricultural societies. It need only be stated here that lambs may be weaned at from two to three months; that the female is fit for procreation at one year and the male at one and a half; that gestation lasts about five months; that one or two young are born at a time; that one male may be kept to 30 females; and that they can produce till the age of 10 or 12, and be fattened with the best advantage at 8 years.—The number of sheep in the United States, as reported by the census of 1870, was 28,477,951. The states having the largest numbers were: Ohio, 4,928,635; California, 2,768,187; New York, 2,181,578; Minnesota, 1,985,906; Pennsylvania, 1,794,301; Indiana, 1,612,680; Illinois, 1,568,286; Missouri, 1,352,001; and Wisconsin, 1,069,282. According to the report of the bureau of agriculture, the total number in the United States in January, 1874, was 34,038,200, valued at about \$89,000,000.

SHEEP'S HEAD, a spiny-rayed fish of the family *sparidae* and genus *sargus* (Cuv.); the scuppaug (*pagrus*) belongs to the same family. The gill covers are unarmed, the palate tooth-

less, the jaws not protractile, and the scales large; the front incisors are cutting, almost like those of man, and there are several rows of rounded molars. This fish (*S. ovis*, Cuv.) is about 20 in. long, though some grow considerably larger; the ground color is light

Sheep's Head (*Sargus ovis*).

gray, with six distinct, dark brown, transverse bands, broad and nearly equidistant, and another across the neck; the head is much darker, the gill covers with silvery and golden reflections, throat somewhat reddish, and irides golden; scales with dark margins; the pectorals nearly colorless, the other fins blackish brown. The body is short and thick, and the back rounded; lips large and fleshy, jaws equal, eyes large, and nostrils high on the head and double; the first 12 rays of the dorsal and first three of the anal strongly spinous, pectorals very long, ventrals stout, with spinous process at base and first ray spinous; air bladder large. The form of the head and blackness of the face give it a slight resemblance to the physiognomy of the sheep. It is caught readily in nets and seines; it is difficult to take with the hook, as the line is very liable to be cut off by the sharp incisors; its food consists of mollusks and crustaceans. Its flesh is highly esteemed. There are several allied species found on the coast from New York to New Orleans, and one in the Mediterranean.

SHEERNESS, a town of Kent, England, at the N. W. end of the island of Sheppey, on the river Medway at its junction with the Thames, 37 m. E. by S. of London; pop. in 1871, 13,956. There is here an extensive naval establishment, defended by batteries mounting 100 guns, the dockyard and buildings in connection with which occupy 60 acres, and have cost since 1815 £3,000,000. There are sometimes as many as 70 ships of war moored at Blackstakes, a little above Sheerness. The town has recently been much improved, and is becoming a favorite watering place. In the time of the commonwealth the ground on which it stands was unoccupied, and after the restoration a small fort was begun, but the Dutch destroyed it in 1667. Soon afterward strong fortifications were constructed and the dockyard was commenced.

SHEFFIELD, a town of Yorkshire, England, in the West riding, at the junction of the Sheaf and three smaller streams with the Don, 141 m. N. N. W. of London; pop. in 1871, 239,946; in 1874 reported at 261,029. The streams which unite here have their source in the surrounding high lands, and supply a large amount of effective water power. The town occupies a natural amphitheatre opening toward the northeast, and was originally confined to the angle between the Don and the Sheaf, but has extended up the slopes of the hills. The streets are well paved and lighted with gas, and the rivers are crossed by fine bridges. The original parish Church was erected in the time of Henry I., and there are several handsome modern churches. In 1872 there were 123 places of worship, of which 28 belonged to the church of England, 62 to various denominations of Methodists, 13 to the Congregationalists, 4 to the Baptists, and 4 to the Roman Catholics. The higher educational institutions are the People's college, the church of England institute, the Wesley college, the collegiate school, the old endowed grammar school, the mechanics' institution, and the government school of art, one of the best conducted in England. Its benevolent institutions are numerous and well sustained. A great music hall was opened in 1873, and a public park in 1874. The town, partly from the want of suitable drainage and partly from the unhealthfulness of some of the occupations, has a higher rate of mortality than most of the large towns of England. The river Don was made navigable to within 8 m. in 1751, and a canal subsequently prolonged the navigation to the town. The canal basin is accessible to vessels of 60 tons. Sheffield has for several centuries been renowned for its knives, and it is the chief seat of the English manufacture of cast, shear, and blister steel of all kinds, steel wire, cutlery and tools of almost every variety, railway and carriage springs and buffers, and many other kinds of steel and iron ware, as well as all classes of silver, silver-plated, electro-plated, German silver, britannia, and other white metal goods. Britannia metal and the process of silver-plating were invented here. Snuff is largely produced. There are extensive iron and brass foundries, and plates have been made for iron-clad ships. Among other important manufactures are those of optical instruments, especially spectacle glasses, and of articles in great variety from pressed horns and hoofs. The cutlers' company had its origin in the 16th century, and was incorporated by statute in the reign of James I. Its restrictions, which interfered with the prosperity of the trade, were mitigated in 1801, and wholly abolished in 1814. It is the trustee of several important charities, besides which its only duties are the granting of trade marks to cutlers.—Sheffield was a Saxon town, and received a charter as a market town from Edward I. in 1296. Early in the 15th century it

came under the control of the earls of Shrewsbury, who had a castle in the town, and a manor house in a park a mile east, in one or the other of which the greater part of the captivity of Mary, queen of Scots, was passed. The castle was demolished in 1648 by order of parliament, and the park divided into farms in 1707. The great development of the town as a centre of manufacture has made it the scene of some of the most violent demonstrations in connection with the trades unions. In 1864 the bursting of the Bradfield reservoir in the hills above it resulted in the loss of 300 lives and of property valued at about £1,000,000.

SHEFFIELD, John. See BUCKINGHAM, or BUCKINGHAMSHIRE, DUKE OF.

SHEFFORD, a S. W. county of Quebec, Canada; area, 559 sq. m.; pop. in 1871, 19,077, of whom 12,683 were of French, 3,020 of English, 2,510 of Irish, and 610 of Scotch origin. It is drained by the Yamaska river, and is traversed by the Stanstead, Shefford, and Chambly railway. Capital, Waterloo.

SHEIL, Richard Lalor, an Irish orator, born near Waterford, Aug. 17, 1791, died in Florence, May 23, 1851. He was educated at the Jesuit school of Stonyhurst, Lancashire, and at Trinity college, Dublin, where he graduated in 1811; and he was called to the bar at Lincoln's Inn in 1814. Between 1814 and 1822 he produced six dramas, "Adelaide" (1816), "The Apostate" (1817), "Bellamira" (1818), "Evadne" (1819), founded on Shirley's "Traitor," "Montoni" (1820), and "The Huguenot" (1822), all of which but the last obtained a decided success. In 1822 also appeared the first of a series of "Sketches of the Irish Bar," since collected and edited by R. S. Mackenzie (2 vols. 12mo, New York, 1854; London, 1855), which are among his most successful literary performances. About this time he began to be known in Ireland and England as a political orator and agitator, and also by his forensic efforts. He joined the Catholic association in 1822, and in 1825 was chosen with O'Connell to plead at the bar of the house of commons against its suppression. In 1829 he entered parliament, and almost immediately took his place as a most brilliant and impulsive speaker. After seconding O'Connell in the repeal agitation, he accepted a sinecure office under the Melbourne ministry, and in 1839 was made a privy councillor. He was appointed master of the mint by the Russell ministry, and in 1850 accepted the mission to Florence. His memoirs have been written by W. T. McCullagh (2 vols., London, 1855).

SHEKEL (Heb., weight), the Hebrew unit of weight, and hence, as payments were originally made by weight, also of money. It was equal to 220 grains troy, or about $\frac{1}{3}$ oz. avoirdupois, which is the weight of the earliest coin of the name known, the silver shekel of Simon Maccabæus. Its value, as differently stated, was from 50 to 62 $\frac{1}{2}$ cts. The golden shekel was of a little more than half this weight, and

worth about \$4. Both as weight and money it was divided in reckoning into the beka, reba, and gerah, respectively $\frac{1}{2}$, $\frac{1}{4}$, and $\frac{1}{16}$ of a shekel. The Scriptures mention the sacred and the royal shekel, which are supposed by some to be two standards of weight; the relative value was supposed by Michaelis to have been as 5 to 3.

SHELBURNE, a S. W. county of Nova Scotia, Canada, bordering on the Atlantic ocean; area, 948 sq. m.; pop. in 1871, 12,417, of whom 7,426 were of English, 1,780 of Scotch, 1,325 of Irish, and 1,064 of German origin or descent. The coast is deeply indented with numerous excellent harbors, into which flow several considerable streams. The surface is mountainous along the shore, but further inland it is mostly level. Capital, Shelburne.

SHELBURNE, William Petty, earl of. See LANS-DOWNE.

SHELBY, the name of counties in nine of the United States. **I.** A central county of Alabama, bounded E. by the Coosa river and intersected by the Cahawba; area, about 900 sq. m.; pop. in 1870, 12,218, of whom 3,378 were colored. The surface is hilly with considerable forests, and the soil is well watered and highly fertile. Coal and iron ore abound. It is traversed by the Selma, Rome, and Dalton, and the South and North Alabama railroads. The chief productions in 1870 were 30,275 bushels of wheat, 221,618 of Indian corn, 26,189 of oats, 22,358 of sweet potatoes, 2,194 bales of cotton, 3,710 lbs. of tobacco, and 6,283 of wool. There were 1,174 horses, 2,680 milch cows, 3,923 other cattle, 3,524 sheep, and 9,787 swine; 1 manufactory of cotton thread, 1 of pig and 1 of cast iron, 2 of lime, and 5 saw mills. Capital, Columbiana. **II.** An E. county of Texas, bordering on Louisiana, bounded E. by the Sabine and W. by the Attoyac river; area, 844 sq. m.; pop. in 1870, 5,732, of whom 1,755 were colored. The surface is generally level and the soil rich. The chief productions in 1870 were 168,827 bushels of Indian corn, 21,416 of sweet potatoes, and 4,090 bales of cotton. There were 1,597 horses, 3,219 milch cows, 1,058 working oxen, 7,276 other cattle, 2,173 sheep, and 13,709 swine. Capital, Shelbyville. **III.** A S. W. county of Tennessee, bordering on Mississippi, bounded W. by the Mississippi river, which separates it from Arkansas, intersected by Loosahatchee and Wolf rivers, and traversed by several railroads; area, 720 sq. m.; pop. in 1870, 76,378, of whom 36,640 were colored. The surface is level and the soil very fertile. The chief productions in 1870 were 19,025 bushels of wheat, 940,796 of Indian corn, 22,419 of Irish and 50,747 of sweet potatoes, 32,434 bales of cotton, and 1,264 lbs. of wool. There were 4,857 horses, 3,715 milch cows, 6,117 other cattle, 17,591 sheep, and 33,687 swine. There are many manufacturing establishments, chiefly in Memphis, the county seat. **IV.** A N. county of Kentucky, drained

by Beech and other large creeks; area, about 565 sq. m.; pop. in 1870, 15,733, of whom 5,383 were colored. The surface is hilly and diversified with fine forests; the soil is very rich. It is traversed by the Louisville, Cincinnati, and Lexington railroad. The chief productions in 1870 were 171,562 bushels of wheat, 62,097 of rye, 1,125,787 of Indian corn, 156,935 of oats, 240,435 lbs. of tobacco, 37,512 of wool, 229,050 of butter, and 13,497 gallons of sorghum molasses. There were 6,781 horses, 2,022 mules and asses, 4,191 milch cows, 8,980 other cattle, 9,436 sheep, and 39,852 swine; 9 manufactories of carriages and wagons, 8 of saddlery and harness, 1 flour mill, and 4 saw mills. Capital, Shelbyville. **V.** A W. county of Ohio, intersected by the Miami river; area, 425 sq. m.; pop. in 1870, 20,748. The N. part is level, the S. undulating, and the soil fertile. It is traversed by the Miami canal and the Cleveland, Columbus, Cincinnati, and Indianapolis, and the Dayton and Michigan railroads. The chief productions in 1873 were 331,293 bushels of wheat, 831,417 of Indian corn, 253,484 of oats, 37,323 of barley, 35,095 of potatoes, 11,404 tons of hay, 131,970 lbs. of tobacco, 67,709 of wool, 336,884 of butter, and 9,345 gallons of sorghum molasses. In 1874 there were 7,890 horses, 14,605 cattle, 22,461 sheep, and 25,169 hogs. In 1870 there were 2 manufactories of agricultural implements, 14 of carriages and wagons, 1 of woollen goods, 3 tanneries, 7 flour mills, and 19 saw mills. Capital, Sidney. **VI.** A S. E. county of Indiana, drained by the Blue river and numerous other streams, and traversed by several railroads; area, about 400 sq. m.; pop. in 1870, 21,892. The surface is level and the soil fertile. The chief productions in 1870 were 669,509 bushels of wheat, 1,509,448 of Indian corn, 40,227 of oats, 12,754 of barley, 8,574 tons of hay, 22,730 lbs. of tobacco, 39,494 of wool, 414,863 of butter, and 31,637 gallons of sorghum molasses. There were 7,739 horses, 5,202 milch cows, 7,928 other cattle, 14,250 sheep, and 34,918 swine; 11 manufactories of carriages and wagons, 2 of woollen goods, 1 distillery, 9 flour mills, 16 saw mills, and 1 planing mill. Capital, Shelbyville. **VII.** A central county of Illinois, intersected by the Kaskaskia and Little Wabash rivers, and traversed by several railroads; area, about 800 sq. m.; pop. in 1870, 25,476. The surface is almost level, and the soil fertile. The chief productions in 1870 were 467,541 bushels of wheat, 2,082,578 of Indian corn, 637,812 of oats, 138,314 of potatoes, 23,687 tons of hay, 6,469 lbs. of tobacco, 222,042 of wool, 368,649 of butter, and 75,183 gallons of sorghum molasses. There were 13,059 horses, 1,271 mules and asses, 7,513 milch cows, 11,204 other cattle, 62,868 sheep, and 43,411 swine; 6 manufactories of carriages and wagons, 1 of woollen goods, 2 brick yards, 9 flour mills, and 9 saw mills. Capital, Shelbyville. **VIII.** A W. county of Iowa, drained by Boyer and other rivers;

area, about 625 sq. m.; pop. in 1870, 2,540. The surface is rolling and the soil fertile. A portion of the county is traversed by the Chicago, Rock Island, and Pacific railroad. The chief productions in 1870 were 155,320 bushels of Indian corn, 25,594 of oats, 6,492 tons of hay, 11,103 lbs. of wool, 61,834 of butter, and 3,002 gallons of sorghum molasses. There were 1,199 horses, 1,151 milch cows, 1,516 other cattle, 2,806 sheep, and 2,060 swine. Capital, Harlan. **IX.** A N. E. county of Missouri, intersected by the North fork of Salt river and the South Fabius river, and by the Hannibal and St. Joseph railroad; area, about 520 sq. m.; pop. in 1870, 10,119, of whom 571 were colored. The surface is moderately hilly and the soil good. Bituminous coal and limestone are abundant, and timber is scarce. The chief productions in 1870 were 41,258 bushels of wheat, 297,982 of Indian corn, 161,559 of oats, 18,715 tons of hay, 36,596 lbs. of wool, 146,905 of butter, and 9,413 gallons of sorghum molasses. There were 3,741 horses, 541 mules and asses, 3,504 milch cows, 7,776 other cattle, 13,028 sheep, and 14,223 swine. Capital, Shelbyville.

SHELBY, Isaac, an American officer, born near Hagerstown, Md., Dec. 11, 1750, died in Lincoln co., Ky., July 18, 1826. He removed to the west in 1771, and in 1774 served as a lieutenant in an expedition against the Indians. When the revolution broke out he became captain of a military company in Virginia, and in 1777 was placed in charge of the commissary department for the frontier militia. In 1779 he was elected to the house of delegates of Virginia, and received a major's commission, and the next year was made a colonel. For his bravery at the battle of King's Mountain, Oct. 7, 1780, he received a vote of thanks and a sword from the legislature of North Carolina, of which he was elected a member in 1781 and 1782. In 1781 he served in Marion's campaign. On the organization of the state of Kentucky in 1792 he was chosen governor, and held the office four years, and again from 1812 to 1816. In 1813 he joined Gen. Harrison at the head of 4,000 Kentuckians, served at the battle of the Thames, and received a gold medal from congress.

SHELBYVILLE, a city and the county seat of Shelby co., Indiana, on the Blue river and the Indianapolis, Cincinnati, and Lafayette railroad, at the junction of a branch of the Jeffersonville, Madison, and Indianapolis line, 27 m. S. E. of Indianapolis; pop. in 1870, 2,731; in 1875, estimated by local authorities at 4,000. It is surrounded by a rich farming country, is lighted with gas, and has a good fire department. It contains a planing mill, two saw mills, three flouring and grist mills, two banks, five hotels, a seminary, three weekly newspapers, and seven churches.

SHELDRAKE, or *Shieldrake*, the common name of the river ducks of the subfamily *anatinae* and of the genera *tadorna* (Leach) and *casarka*

(Bonap.). In *tadorna* the bill is shorter than the head, higher at the base than broad, with culmen concave in the middle, depressed, curved upward at the tip, which is suddenly hooked and has a strong narrow nail; lamellæ slender and widely set; nostrils large, near the culmen; wings moderate, pointed, the second quill longest, and armed on the shoulder with a tubercle; tail moderate, nearly even; tarsi strong, shorter than the middle toe; toes short, fully webbed; hind toe elevated, slightly lobed; claws moderate and curved. They are widely distributed over the old world, on the seacoast as well as on rivers and lakes, migrating in winter from the north; they feed on marine plants and worms, crustaceans, and mollusks; the nest is made of grass lined with down, and is often placed in the deserted burrows of rabbits and other rodents; they lay 12 to 14 eggs. The common sheldrake (*T. vulpanser*, Flem.) is one of the handsomest of water fowl, the colors being brilliant and pure, and strongly contrasted. In the male the bill is vermilion; the head and upper neck green bounded by a

Common Sheldrake (*Tadorna vulpanser*).

white collar, below which is another of rich chestnut covering the upper breast and back; rest of back, rump, and upper tail coverts white; scapulars nearly black, outer webs of long tertials chestnut, point of wing and its coverts white, primaries dark brown, and speculum green; tail white, tipped with black; abdomen rich dark brown; sides, vent, and under tail coverts white; the length is 24 to 26 in.; the female is smaller and not so bright, and the young are more brownish. The windpipe is about 10 in. long, having on each side at its lower portion a hollow, globular, bony protuberance, generally much larger on one side than the other. The note is a shrill whistle; the flesh is coarse, dark, and of unpleasant odor and flavor; the eggs are shining white, 2¾ by 2 in.; incubation lasts 30 days, both sexes sitting; they are easily domesticated, and are often raised by hens. Yarrell thinks the names are derived from their favorite shell food, and from their frequent use on heraldic shields; they are also called burrow ducks from their common places of breeding, also

skeling geese in Scotland, and sly geese (from their devices for leading intruders from their nests and young) in the Orkney islands. Two other species are found in Australia.—In the genus *casarka* the bill is as long as the head, nearly straight, the width equal to the height at the base, the anterior half depressed, scarcely curved upward at tip, which has a strong and broad nail; wings moderate, the second quill the longest; tail short and rounded; tarsi robust, shorter than the middle toe; toes long, fully webbed; hind toe long, elevated, and lobed. The ruddy sheldrake (*C. rutila*, Bonap.) is about the same size as the last, with similar breeding habits; in the male the bill is lead-colored; the head, cheeks, and chin buff, becoming orange brown at the lower part of the neck all round, where there is a ring of black; the back, tertials, breast, and under parts like the head; wing coverts pale buff white; primaries and tail dark leaden gray, secondaries lighter, and speculum brilliant green; the female is rather smaller and lighter colored, with white on the throat and wings, but without the black collar. It is sometimes called collared duck, and ruddy goose; it is a native of eastern Europe and western Asia, coming as far west as England and south to Italy and Africa; it is fond of breeding in the holes of marmots in river banks, and the eggs are 8 to 10. Other species are found in Australia and New Zealand, and they all resemble geese in general form, and especially in the females having the plumage colored nearly like the males.—In America the name of sheldrake is given to the red-breasted merganser, which resembles the European sheldrake only in the color of its breast. (See MERGANSER.)

SHELL LAC. See LAC.

SHELLEY. I. Percy Bysshe, an English poet, born at Field Place, near Horsham, Sussex, Aug. 4, 1792, drowned in the bay of Spezia, July 8, 1822. His ancestors had long been large landholders in Sussex. His father, Sir Timothy Shelley, was a country gentleman, who had studied at Oxford. Bysshe was sent in his sixth year to a day school near home, and in his tenth to a seminary at Brentford, where he excelled in his studies. At the age of 13 he went to Eton, where he refused to fag, and consequently was harshly treated by his schoolfellows, till he alarmed them by his storms of anger or won their love by his kindness. He was already in love with Miss Grove, a cousin of his own age, with whom he wrote a romance entitled "Zastrozzi" (London, 1810), with the payment for which he gave a magnificent banquet to his friends. He wrote another romance, "St. Irvyne, or the Rosicrucian" (London, 1811), translated a portion of Pliny's "Natural History," and composed in conjunction with Capt. Medwin the poem of "Ahasuerus, or the Wandering Jew," a portion of which was afterward published; but his greatest passion was for chemistry, and he continued eagerly to experiment with elec-

tricity and acids after his return home in 1809. In 1810 he went to Oxford, and became an undergraduate of University college. At first devoted to physics, he abandoned them for metaphysics. Hume and the French exponents of Locke were his text books, and he soon rushed to materialism and atheism. At the age of 17, says De Quincey, satisfied that atheism was the sheet anchor of the world, he determined to accomplish a general apostasy successively in the university, the church of England, and the whole Christian world. He began with printing a pamphlet of two pages on the "Necessity of Atheism," setting forth the defective logic of the usual arguments for the divine existence. He sent it with a letter to the heads of colleges and professors of the university, inviting them to notify him of their assent to the accompanying argument; for this he was expelled, and ordered to quit the college by the next morning. His father at first forbade his appearance at Field Place. All communication was forbidden between him and Miss Grove, who soon married another. He took lodgings in Poland street, London, and his sisters, who were at school at Brompton, sent him small sums saved from their pocket money, the bearer being their school-mate Harriet Westbrook, a beautiful daughter of a retired hotel-keeper, residing in London; and after his reconciliation with his father, who settled upon him an allowance of £200 a year, he suddenly eloped with her and married her at Greta Green. He was aged 19, and she 16. The young pair went to Edinburgh, thence to York, and at length fixed their residence at Keswick. There Shelley became intimate with Southey and De Quincey, and received many favors from the duke of Norfolk. He had already obtained the friendship of Leigh Hunt, and proposed to him a scheme for forming an association of liberals; and he began a correspondence with Godwin, whose advice probably saved him from extreme imprudence in the championship of Irish wrongs, when soon after he removed to Dublin. There, in February, 1812, he published a pamphlet entitled "An Address to the Irish People," copies of which he threw from his window and distributed to passers on the street. The police suggested to him the propriety of quitting Ireland, and he resided successively in the isle of Man, in North Wales, and in Plymouth. From the last named place he addressed an eloquent letter to Lord Ellenborough against his sentence on the publisher of the third part of Paine's "Age of Reason." Soon afterward he took a cottage in Tanyrallt, Carnarvonshire; and prior to May, 1813, he had visited London, resided again in Dublin, made a tour to the lakes of Killarney, and returned to London. In Tanyrallt, as elsewhere, he visited and relieved the poor and suffering. A mysterious attempt on his life, which was never explained, occasioned his immediate removal. In London was born his daughter,

Ianthe Eliza. He soon after removed to the cottage of High Elms in Berkshire, where he passed the summer, with the exception of visits to London and Field Place. Toward the close of 1813 the estrangement which had been slowly growing between him and his wife resulted in their separation by mutual consent, and she returned to her father's house, where she gave birth to a second child, which died in 1826. He was soon after travelling abroad, chiefly in Switzerland, with Mary, afterward the second Mrs. Shelley, daughter of William Godwin and Mary Wollstonecraft, all of whom deemed marriage a useless institution. His father, succeeding to the family estates, settled on him from this time an allowance of £1,000 a year. In the winter he frequented a hospital to acquire some knowledge of surgery, that he might become more serviceable to the poor; made several trips in England in 1815; and again visited Switzerland in 1816, where he first met Byron. The same year his wife drowned herself. He now married his second wife, who had been his companion for two years, and fixed his residence in the neighborhood of Marlow in Buckinghamshire. He claimed the custody of his children, which was refused by the court of chancery on the ground of the alleged depravity of his religious and moral opinions, and after this decision he again left England. He had become acquainted with Keats, whose genius he defended against the reviewers, and afterward wrote to his memory the dirge of "Adonais." In 1810 he had published at Oxford "Posthumous Fragments of Margaret Nicholson," a small volume of poems; and in September of that year, in London, "Original Poetry, by Victor and Cazire," of which about 100 copies got into circulation before he suppressed it, but none can now be found. He had commenced at the age of 18, and completed in 1812, a poem in the rhythm of Southey's "Thalaba," entitled "Queen Mab." It was printed privately in 1813, and an edition was surreptitiously issued in 1821, when he was in Italy. He applied to chancery for an injunction to restrain the sale, which was refused on the ground that the law could give no protection to a heretical book, nor even recognize it except by prosecution. In 1815 he wrote at Bishopsgate, on the Thames, his poem of "Alastor, or the Spirit of Solitude." At Marlow he wrote "The Revolt of Islam." There he suffered a severe attack of ophthalmia, caught while visiting the cottages of the poor. In 1818 he left England, never to return. At Lucca he completed the poem of "Julian and Maddalo," a dialogue between himself and Lord Byron, and began his "Prometheus Unbound," which was finished in Rome in 1819 (London, 1821). His next production was "The Cenci," a tragedy repulsive in its subject, but the most elaborate in execution of all his writings. In 1819 he wrote "The Witch of Atlas" in three days after a pedestrian excursion, and in 1821 produced his

"Epipsychidion," "Adonais," and "Hellas." Among his minor poems, the most exquisite and original are the "Address to the Skylark," "The Sensitive Plant," and "The Cloud." He had renewed his intimacy with Byron in Italy, and enjoyed boating as his favorite amusement. On July 8, 1822, he sailed with his friend Williams, in a boat of peculiar build, and requiring skilful management, from Leghorn for Lerici. In a sudden squall the boat disappeared, and the bodies of Shelley and his companions were washed ashore. The quarantine regulations of Tuscany required that everything drifting from the sea should be burned, and the remains of the poet were therefore reduced to ashes on a funeral pile, after the ancient fashion, in the presence of Lord Byron, Leigh Hunt, and Mr. Trelawney. The ashes were deposited in the Protestant burial ground at Rome, near the grave of Keats, with the inscription: *Cor Cordium*. His reputation both as a poet and a man has risen as the misapprehensions of his contemporaries have passed away, and his sincerity, benevolence, noble aims, and peculiar graces of character and genius have been fully recognized.—Mrs. Shelley published an edition of his poetical works, with biographical notes, in 1839, and a selection from his letters, translations, and prose writings, in 1840. The first complete edition of his works, from the original editions, was edited by R. H. Shepherd (4 vols., London, 1875). See also the "Life" by Capt. Thomas Medwin (London, 1847); "Recollections of the Last Days of Shelley and Byron," by E. J. Trelawney (London and Boston, 1858); the unfinished "Life of Shelley," by Thomas Jefferson Hogg (2 vols., London, 1858); the "Shelley Memorials," by Lady Shelley (London and Boston, 1859); and "Shelley's Early Life, from Original Sources," by Denis Florence Mac-Carthy (London, 1872). **II. Mary Wollstonecraft Godwin**, an English authoress, second wife of the preceding, born in London in 1797, died there, Feb. 1, 1851. She was the daughter of William Godwin and Mary Wollstonecraft, received a careful and peculiar education, and married Shelley in 1816, after having lived with him two years previous to his first wife's death. In 1816, on the lake of Geneva, she joined in a compact with Shelley and Byron each to write a romance in imitation of the German ghost stories which they were reading. The result was her novel of "Frankenstein" (London, 1818), the hero of which discovers the secret of generation and life, and creates a man by the resources of natural philosophy, who proves to be a powerful and mischievous monster. She completed the novel of "Valperga" just before the death of Shelley, and afterward published "The Last Man," "Lodore" (1835), and "The Fortunes of Perkin Warbeck." She also wrote a series of biographies of foreign artists and poets for the "Cabinet Cyclopædia" (1835), and "Rambles in Germany and Italy" (1844), and edited Shelley's works (2 vols., 1839-'40).

SHELTON, Frederick William, an American author, born at Jamaica, Long Island, N. Y., about 1814. He graduated at the college of New Jersey in 1834, took orders in the Protestant Episcopal church in 1847, and has been successively settled at Huntington, Long Island, at Fishkill on the Hudson, and at Montpelier, Vt., whither he went in 1854. He now (1875) resides at Carthage Landing, Dutchess co., N. Y. He has published "The Trollopian, or Travelling Gentleman in America" (New York, 1837), a satirical poem; "Salander and the Dragon, a Romance" (1851); "Chryselline, or the Heiress of Fall-Down Castle" (1854); "The Rector of St. Bardolph's, or Superannuated," and "Up the River" (1853), a series of rural sketches; and "Peeps from the Belfry, or the Parish Sketch Book" (1855).

SHEM (Heb., name, or fame), one of the three sons of Noah, according to most commentators the eldest. He was the progenitor of the southwestern nations of Asia, being the father of Elam (Susiana), Ashur (Assyria), Arphaxad (according to Josephus, Chaldea), from whom descended the Hebrews and Arabs, Lud (Lydia), and Aram (Syria). The region occupied by the Biblical Shemites or Semites thus extended from the mountains E. of the Tigris to the western offshoots of the Taurus, and from the Armenian mountains to the southern extremities of the Arabian peninsula. (See SEMITIC RACE AND LANGUAGES.)

SHENANDOAH, a river of Virginia, the principal tributary of the Potomac. The main river, or South fork, rises in Augusta and Rockingham cos. in three streams which unite near Port Republic, Rockingham co., flows N. E. through the valley of Virginia, W. of and nearly parallel with the Blue Ridge, receives the North fork at Front Royal, Warren co., and falls into the Potomac at Harper's Ferry, W. Va. Its length from Port Republic is about 170 m., and it is navigated by small boats, called gondolas, for more than 100 m. above Front Royal. It passes through the richest portion of Virginia, and affords immense water power. The valley of the Shenandoah was very conspicuous in the military operations of the civil war.

SHENANDOAH, a N. county of Virginia, intersected by the North fork of the Shenandoah river; area, about 500 sq. m.; pop. in 1870, 14,936, of whom 676 were colored. The surface is hilly and the soil generally fertile. Iron ore, lead, copper, coal, and limestone are found. It is traversed by the Winchester, Potomac, and Harrisonburg division of the Baltimore and Ohio railroad. The chief productions in 1870 were 239,045 bushels of wheat, 19,860 of rye, 154,313 of Indian corn, 81,023 of oats, 8,329 tons of hay, 18,757 lbs. of wool, and 165,338 of butter. There were 3,466 horses, 9,946 cattle, 6,645 sheep, and 9,364 swine; 1 manufactory of bar and 1 of pig iron, 7 of stone and earthenware, 10 flour mills, and 3 saw mills. Capital, Woodstock.

SHENSTONE, William, an English poet, born at the Leasowes in Hales-Owen, Shropshire, in November, 1714, died there, Feb. 11, 1763. He passed several years at Pembroke college, Oxford, but never took a degree. About 1745 he retired to his hereditary estate of the Leasowes, which it thenceforth became the business of his life to beautify. He wrote elegies, odes, ballads, and miscellaneous pieces, but is best known by the "Schoolmistress," a poem published in 1742. Dodsley published his works and letters (3 vols. 8vo, 1764-'9). An edition of his poems, with a memoir by the Rev. George Gilfillan, appeared at Edinburgh in 1854, and a new edition of his "Essays on Men and Manners," &c., at London in 1868.

SHEPARD, Charles Upham, an American physicist, born at Little Compton, R. I., June 29, 1804. He graduated at Amherst college in 1824, taught botany and mineralogy in Boston, was for two years assistant in the laboratory of Prof. Silliman at Yale college, and took charge for one year of an institution opened in New Haven by James Brewster for popular lectures on science. In the winter of 1832-'3 Mr. Shepard, under a commission from the United States government, investigated the culture of the sugar cane and the manufacture of sugar in the southern states, and incorporated the results of his observations in Prof. Silliman's report to the secretary of the treasury in 1833. He had previously been appointed lecturer on natural history in Yale college, a post which he held till 1847. From 1834 to 1861 he was professor of chemistry in the Charleston medical college, S. C. In 1835 he was appointed associate of Dr. Percival in the state geological survey of Connecticut. In 1845 he was chosen professor of chemistry and natural history in Amherst college, where he is now (1875) professor of natural history. His collection of minerals and meteorites, now deposited in Amherst college, is the finest in the United States, and surpassed in Europe only by those of the British museum and the imperial cabinet of Vienna. He has published "Treatise on Mineralogy" (1832; 3d ed., enlarged, 1855), a report on the geology of Connecticut (1837), and numerous scientific papers.

SHERBROOKE. I. A S. county of Quebec, Canada, drained by the St. Francis and Magog rivers; area, 219 sq. m.; pop. in 1871, 8,516, of whom 3,544 were of French, 2,442 of English, 1,601 of Irish, and 777 of Scotch origin or descent. It is traversed by the Grand Trunk, the Massawippi Valley, and the St. Francis and Lake Megantic International railways. **II.** A town, capital of the county, on both sides of the river Magog, at its entrance into the St. Francis, on the Portland division of the Grand Trunk railway, at the intersection of the Massawippi Valley railway, 80 m. E. by S. of Montreal; pop. in 1871, 4,432. It contains manufactories of woollen and cotton cloths, flannels, iron castings, machinery, axes, pails, &c., several saw mills and breweries, a

bank, a branch bank, an academy, and three weekly newspapers (one French).

SHERBURNE, a central county of Minnesota, bounded S. W. by the Mississippi and intersected by Snake river; area, 445 sq. m.; pop. in 1870, 2,050. It contains several small lakes. The surface is diversified and the soil productive. It is traversed by the St. Paul and Pacific railroad. The chief productions in 1870 were 26,457 bushels of wheat, 37,006 of Indian corn, 17,797 of oats, 17,987 of potatoes, 8,303 tons of hay, 2,556 lbs. of wool, and 56,610 of butter. There were 412 horses, 716 milch cows, 1,490 other cattle, 1,112 sheep, and 542 swine. Capital, Orono.

SHERIDAN. I. An unorganized N. W. county of Kansas; area, 900 sq. m. It is drained by Prairie Dog creek, the North and South forks of Solomon river, and the Saline river. It consists of undulating and fertile prairies, and is well adapted to grazing. **II.** A N. central county of Dakota, recently formed and not included in the census of 1870; area, about 1,750 sq. m. It contains several small lakes, and the N. part is watered by one of the head streams of the Cheyenne and by an affluent of Mouse river. The W. part is occupied by the Plateau du Coteau du Missouri.

SHERIDAN, Philip Henry, an American soldier, born in Somerset, Perry co., Ohio, March 6, 1831. He graduated at West Point in 1853, served in Texas in 1854-'5, and on the Pacific coast till May 14, 1861, when he was made captain of the 13th infantry, chief quartermaster and commissary of the army of S. W. Missouri, and subsequently quartermaster to Gen. Halleck in the Mississippi campaign of the spring of 1862. On May 25, 1862, he was made colonel of the 2d Michigan volunteer cavalry, and took part in the pursuit of the confederates from Corinth, May 30 to June 10, and in the engagement at Booneville, July 1, when he was made brigadier general of volunteers. In command of the 11th division of the army of the Ohio he led the advance into Kentucky, and was in the battle of Perryville, Oct. 8, and in the subsequent march to the relief of Nashville. Assigned to the army of the Cumberland, his division was in the campaign of Tennessee from November, 1862, to September, 1863, taking active part in the battle of Murfreesboro (see MURFREESBORO), when he was made major general of volunteers. He captured a train and prisoners at Eagleville in March; crossed the Cumberland mountains and Tennessee river in August; took part in the battle of Chickamauga, Sept. 19, 20, and in the operations about Chattanooga, including the battle of Missionary ridge, Nov. 23-25; and was subsequently engaged in E. Tennessee till March, 1864. From April 4 to Aug. 3 he was in command of the cavalry corps of the army of the Potomac, and with his 10,000 men was actively employed in operations in the Wilderness, and between it and Richmond, in May, June, and July. While mainly employed

in reconnoitring and in protecting the flank of the army, his corps made several vigorous raids, cutting off railway connections and capturing or destroying stores, was more than 20 times engaged with the confederate cavalry, and took an important part in the actions in and about Cold Harbor. On Aug. 4 he was appointed to the command of the army of the Shenandoah, and on the 7th to that of the middle military division. He defeated Early on the Opequan, Sept. 19, for which he was made a brigadier general in the United States army; at Fisher's Hill, Sept. 22; and at Cedar creek, Oct. 19, where he turned a rout into a brilliant victory, for which he received the thanks of congress. On Nov. 8 he was made a major general. From Feb. 27 to March 24, 1865, he was engaged in the raid from Winchester to Petersburg, during which he destroyed the James river and Kanawha canal, cut important railway connections, destroyed military and commissary stores, and had numerous skirmishes with the enemy. From March 25 to April 9 he was in the Richmond campaign. On April 1 he gained the battle of Five Forks, which insured the abandonment by the confederates of Petersburg and Richmond (see PETERSBURG, SIEGE OF), and he led in the pursuit of Lee, and was present at his capitulation, April 9. He was appointed to the command of the military division of the Southwest June 3, and of the military division of the Gulf July 17; of the department of the Gulf Aug. 15, 1866; of the fifth military district, including Louisiana and Texas, March 11, 1867; and of the department of the Missouri, with headquarters at Fort Leavenworth, Sept. 12. On March 4, 1869, he was made lieutenant general and assigned to the command of the division of the Missouri, including the departments of Dakota, of the Missouri, of the Platte, and of Texas, with headquarters at Chicago, which office he still holds (1875). Early in 1875, political disturbances threatening in Louisiana, he was stationed for a few weeks in New Orleans, and then returned to his command in Chicago.

SHERIDAN. I. Thomas, an Irish clergyman, born in county Cavan about 1684, died in Dublin, Sept. 10, 1738. He was educated by private charity at Trinity college, Dublin, took orders, received the degree of D. D., and was named chaplain to the lord lieutenant. Losing his college fellowship by marriage, he opened a school in Dublin, which proved highly successful, but finally ruined it by negligence and extravagance. In 1725 he was presented to a living through the influence of Dean Swift, but lost his chaplaincy by preaching a sermon on the birthday of George I. from the text: "Sufficient unto the day is the evil thereof." After several changes of fortune he died in great poverty and distress, having maintained through all a gay and careless cheerfulness, not allowing a day to pass, according to Lord Cork, "without a rebus, an anagram, or a madri-

gal." He published a translation of Persius in prose, and one of Sophocles's "Philoctetes" in verse. Many of his letters are included in Swift's "Miscellanies." **II. Thomas**, an elocutionist, son of the preceding, born at Quilca, the residence of Dean Swift, near Dublin, in 1721, died at Margate, Aug. 14, 1788. He was educated at Westminster school and at Trinity college, Dublin, and in 1743 went upon the stage. In 1744 he played at Covent Garden theatre, and in 1745 at Drury Lane, and was set up as a rival of Garrick. For eight years he managed the Dublin theatre, but in 1754, disregarding a clamor for the repeated recitation of certain popular and political passages in a play, a fierce riot broke out, and he retired. He resumed the management in the next year, but the erection of a rival theatre and other causes ruined his business. He then engaged with great success in lecturing on elocution in London, Oxford, Cambridge, and Scotland. He received a pension from the crown on the accession of George III. In 1760 he appeared again briefly at Drury Lane, when his quarrel with Garrick was renewed. He subsequently appeared at the Haymarket, and his last performance was at Covent Garden in 1776. After Garrick's retirement in that year, Sheridan was for three years manager of Drury Lane, his son Richard Brinsley being lessee. He then retired altogether from the theatre, and in 1780 published his "Complete Dictionary of the English Language, both with regard to Sound and Meaning, one main Object of which is to establish a plain and permanent Standard of Pronunciation." Among his other works are: "Lectures on the Art of Reading," "Course of Lectures on Elocution," and a "Life of Swift." **III. Frances**, a novelist, wife of the preceding, born in Ireland in 1724, of English parentage, died in Blois, France, in September, 1766. At the age of 15 she wrote a romance, "Eugenia and Adelaide," which was afterward adapted for the stage by her daughter as a comic drama, and acted with success in Dublin. She became acquainted with Sheridan by means of a pamphlet which she published in his defence during his managerial troubles in Dublin, and they were soon after married. Her romances, "Sidney Biddulph" and "Nourjahad," are still admired. She was also the author of two less successful comedies, "The Discovery" and "The Dupe," and wrote, but never published, "The Trip to Bath," from which her son is supposed to have derived hints for his "Rivals." **IV. Richard Brinsley**, an English dramatist and politician, son of the preceding, born in Dublin in September, 1751, died in London, July 7, 1816. In 1762 he was sent to Harrow, whence in his 18th year he went to Bath, where his family had settled, and in conjunction with a friend named Halded wrote some fugitive pieces, and a translation of Aristænetus. He fell in love with Miss Linley, a young and beautiful singer of Bath, and to save her from the persecutions of a lib-

ertine named Matthews he fled with her early in 1772 to France, and they were secretly married at Calais. The result was two duels with Matthews, in the last of which Sheridan was wounded. In 1773 he entered the Middle Temple as a student of law, and shortly afterward was married anew by license, and retired to a cottage at East Burnham. On Jan. 17, 1775, his comedy of "The Rivals" was brought out at Covent Garden, and, though it failed the first night, speedily became the universal favorite it has ever since remained. It was followed the same year by the farce of "St. Patrick's Day, or the Scheming Lieutenant," and the comic opera of "The Duenna," which had the then unparalleled run of 75 representations during the season. In 1776, with his father-in-law and Dr. Ford, he purchased Garrick's share of Drury Lane. In the following year he brought out "The School for Scandal," which placed him at once at the head of comic dramatists. This was followed in 1779 by a monody on the death of Garrick, and the farce of "The Critic." Embracing the principles of the whig party, his first service was in connection with a periodical called "The Englishman." In 1780 he was elected a member of parliament from Stafford, and entered the ranks of the opposition to the administration of Lord North. His first speech, in reply to accusations brought against him for bribery and corruption in securing his election, disappointed both his friends and his enemies. He rarely spoke after this, and only after great preparation. In 1782 Lord North went out of office, and in the short-lived ministry of Rockingham which followed, Sheridan was one of the under-secretaries of state. After the accession of Shelburne to the treasury, he, with most of the friends of Fox, resigned. In the coalition ministry of Fox and North in 1783, Sheridan was secretary of the treasury, but retired on the accession of William Pitt. Parliament having been dissolved, he was one of the few adherents of the coalition that were reelected in 1784. On Feb. 7, 1787, Sheridan brought forward the charge against Warren Hastings touching the spoliation of the begums or princesses of Oude, in an oration which was the greatest effort of his life, but no good report of which exists. In the trial of Hastings Sheridan was one of the managers of the impeachment, and made a second oration little inferior, which lasted four days. In 1790 he was reelected to parliament from Stafford. A rupture took place between him and Burke, caused somewhat by a mutual jealousy, but ostensibly by a difference of opinion on the French revolution. In June, 1792, his wife died, and in 1795 he married a Miss Ogle, daughter of the dean of Winchester. His careless and extravagant style of living resulted in pecuniary embarrassment, and irregularities of his private life placed him under the ban of public opinion. In the house of commons he vehemently assailed the adminis-

tration, but at the time of the mutiny at the Nore lent it his support. In 1799 he brought out the play of "Pizarro," which is largely a translation from Kotzebue. Sheridan supported the short-lived ministry of Addington, and in this differed from Fox, between whom and himself a feeling of reserve and even alienation had been for some time growing. In the ministry of Grenville and Fox, which succeeded the death of Pitt, he accepted the comparatively unimportant office of treasurer of the navy. He was elected from Westminster after a severe contest; but in 1809, while speaking in the house of commons, he saw himself involved in almost total ruin by the burning of Drury Lane theatre, in rebuilding which he had already loaded himself with debt. In 1812 he failed to be reelected from Stafford, and this filled up the measure of his ruin. His health had been destroyed by drink, and his spirits were depressed by harassing duns. His books, his furniture, his presents were sold or passed into the hands of pawnbrokers; even the portrait of his first wife by Reynolds went out of his possession; and he was imprisoned two or three days for debt. While in his last illness an officer arrested him in his bed, and would have carried him to the sponging house had he not been threatened with prosecution by Sheridan's physician. He died near his sick wife, deserted by all except his medical adviser and Peter Moore, Rogers, and Lord Holland, the few friends who had remained faithful to him in his misfortunes. He was buried in the poets' corner in Westminster abbey. His life, by Thomas Moore, was published in 1825, and his "Speeches" were "edited by a Constitutional Friend" (5 vols. 8vo, London, 1816). His "Dramatic Works" form a volume of Bohn's "Standard Library" (1848), and have been edited, with a memoir, by James P. Browne, M. D. (2 vols. 8vo, 1873). A collection of Sheridan's dramas, poems, translations, speeches, and unfinished sketches, with a memoir and a collection of ana, has been edited by F. Stainforth (1874).

SHERIFF (A. S. *scyre*, shire, and *gerefa* or *refa*, keeper or steward), in Great Britain and the United States, the chief officer of a county. The office of sheriff is of ancient Saxon origin, as appears from the composition of the word, which successively assumed the forms of shyre-greve, shiregreve, shirereeve, and shireve. Cowell writes the word shireve, and Blount shirif or shiref. In the Norman period the earl or count (*comes*) was the one to whom was committed the custody of the shire or county; and when in course of time he was relieved of the active functions of the office, they were devolved upon an inferior officer, called therefore *vice-comes*, who is identical with the sheriff. Gradually the earls were discharged not only of the duties of the office but also of the commission, and the sheriffs thus came to be the immediate officers of the crown and not of the earls; and the sheriff

succeeded to almost all the authority, judicial and ministerial, that the *comes* or earl had hitherto possessed. Until the time of Edward II. the sheriff was elected by the inhabitants of the several counties; but a statute of the ninth year of that reign abolished election, and ever since, with few exceptions, the sheriff has been appointed, upon nomination by the king's councillors and the judges of certain ranks, by the approval of the crown. In some cities and towns the sheriff is elected either by the whole body of the freeholders or by some particular body of the corporation. London claims prescriptive right to elect her two sheriffs. The office of sheriff is still in England one of eminent honor, and is conferred on the wealthiest and most notable commoners in the counties.—The English sheriff, the sheriff of the common law, we may say, is the custodian of the county and the conservator of the king's peace therein. In virtue of these functions he is bound to apprehend all disturbers of the peace and bind them to good behavior or commit them for examination, and to arrest and commit all felons. To these ends he has the right to summon to his aid whenever it is necessary the *posse comitatus*, or power of the county, and he has the custody of the county jail. In a ministerial capacity it is his office to execute all writs and processes directed to him by the superior courts of judicature, to take recognizances and bail, to summon juries, and to execute final process and judgments of the courts whether civil or criminal. As king's bailiff, he is to take into his charge all lands falling to the crown under attainders or by escheats, levy all fines and forfeitures, and collect all waifs and estrays. Finally, in his judicial capacity he may adjudicate in certain petty civil suits. He also determines matters touching the election of knights of the shire, of coroners, and other officers.—The sheriff retains in the United States many of the faculties of the sheriff at common law; yet his capacity in all respects is much dependent on the provisions of special statutes. His judicial powers are particularly restricted here; his duties are in fact almost entirely ministerial. Generally in the United States the sheriff, like every other considerable officer, is elected by the whole body of the people, and holds his office for a prescribed term of years. In New York and some other states he is ineligible for the three years next succeeding his term of office. As he cannot perform in his own person the manifold duties of his office, the sheriff may appoint deputies. He is also in some states required to appoint an under sheriff. This officer is the equal of the sheriff himself, and acts in his stead in all respects when he is absent or his office is vacated. The sheriff may create as many general deputies as he thinks proper. The deputy sheriff in this country, though not in England, is an officer known and recognized by the law. He is sep-

arately sworn, and has his distinct rights and liabilities. Primarily, however, the sheriff is responsible for all the deputy's defaults in respect to duties imposed by the law upon the sheriff.—As conservator of the peace it is the duty of the sheriff (and generally speaking the deputy may do what the sheriff may do) to suppress all unlawful assemblages, to quell all riots and affrays, and to arrest and commit to jail, if need be, those engaged in the disturbance of the public order. For any breach of the peace or any crime or misdemeanor committed within his view the sheriff may make an arrest without a warrant. To suppress an affray actually going on, he may even break into a dwelling house, and so he may if he is in fresh pursuit of one who has committed an offence within his view, and there is danger that he may escape if he is not followed. When the breach of the peace has been committed at a time past, it is the sheriff's duty in most cases to provide himself with a warrant before making an arrest. In the service of this process, the sheriff appears, in a ministerial capacity, as the officer of the court which issues it. In making the arrest, the officer ought, properly speaking, to show his warrant, and make known, to a reasonable degree, the contents and purport of it; but every person within his bailiwick is bound to take notice of his official character. If the warrant is issued for the arrest of one who has committed a felony, the sheriff may even break the outer door of a house in order to execute the process. If the warrant of arrest appears upon its face to be defective in any essential respect, it is absolutely void, and all who participate in the execution of it are trespassers. The party arrested under a warrant ought to be brought presently before the court or magistrate who issued the process.—The sheriff's duties and powers in the execution of civil process differ in some respects from those imposed upon him in the execution of process in criminal matters. On the one hand, the officer is liable to the suitor at whose instance the process issues, if through negligence or error he fails to perform his whole duty in the service of it; while he is responsible to the party wronged if he exceeds the power conferred upon him. Wherever then he has reasonable grounds to doubt his authority to act in the premises, the sheriff may ask an indemnity. This is often done in cases where the title to property which is directed to be attached is doubtful, or where the officer questions the identity of a person whom he is ordered to arrest. Service of summons in a suit is made by reading it to the party to whom it is addressed, or ordinarily by delivering to him a copy of it, or by leaving the copy at his last usual place of residence. Attachment of property, as the first step in the suit, is unknown to the common law, and is founded upon statutes. To constitute a valid attachment of personal property, the officer must take actual possession of the goods. The sub-

sequent use of the property by the owner with the officer's permission, when no harm is done to the goods by the using, or even a resumption of the possession by the owner for the purpose of making a delivery subject to the officer's attachment, does not vacate this attachment. A warehouse may be broken into in order to make an attachment of goods deposited there. Goods in a store are well attached by locking the door and taking the key. Shares of stock may be attached by leaving an attested copy of the writ and of the return of the attachment with the treasurer or other clerk of the corporation at the business office. The duties of the sheriff in respect to the drawing of jurors, the service of summonses or subpoenas, and other incidents of the trial of causes, are treated elsewhere. (See **JURY**, and **SUBPOENA**.)—When judgment is docketed in a civil suit against a defendant, it is the sheriff's business to levy the execution which thereupon issues at the instance of the plaintiff. Subject in some respects to the direction of the plaintiff or his attorney, it is the officer's duty to secure the amount of the execution, or the portion of it directed to be collected. If the defendant will not upon request satisfy by payment the amount of the judgment, the sheriff proceeds to satisfy it by the seizure of any goods of the defendant which can be found within the county. The levy may be made at any time before the return day of the execution, but it is expedient to make it at once lest there be any alienation of the property. Any property supposed to belong to the defendant and found in his possession, even though he asserts that it has been sold, mortgaged, or otherwise encumbered, ought to be levied upon by the officer; for if he neglects to do so, he assumes the responsibility of showing that it was in fact exempt; and yet if he does levy and the defendant's statement was indeed true, he becomes liable as trespasser to the real owner or party holding a prior lien, and therefore he has a right to demand indemnity in any such case. In order to make a valid levy, the property ought to be present or in the view of the officer, and he should do some act to signify his claim to control it henceforth. Making a memorandum upon the execution, making an inventory of the goods, or taking a receipt for them from some responsible party, may perhaps be a sufficient indication of a levy. The sheriff may not break into a house to make a levy, but he may enter if the door is open, and remain a reasonable time. The levy in the case of real property, where the statute does not make the judgment itself a sufficient lien, is made by mere indorsement on the execution. Property taken on execution, whether real or personal, is regularly exposed by the sheriff to sale by public auction; and the sheriff can sell such property only for cash.

SHERLOCK. I. William, an English clergyman, born in Southwark about 1641, died in Hampstead, June 19, 1707. He was educated

at Eton and at Peter house, Cambridge, and became rector of the parish of St. George, Botolph lane, London, in 1669, prebend of St. Pancras in the cathedral of St. Paul's in 1681, master of the Temple in 1684, and dean of St. Paul's in 1691. He refused the oaths of allegiance to William and Mary, and was suspended from his preferment, but at length submitted and took them. The principal of his numerous works are: "Case of the Allegiance due to the Sovereign Powers," "Vindication of the Doctrine of the Trinity," and "A Practical Discourse on Death." **II.** Thomas, an English prelate, son of the preceding, born in London in 1678, died there, July 18, 1761. He was educated at Catharine hall, Cambridge, of which college he became master. In 1704 he was made master of the Temple, in 1714 vice chancellor of the university, and in 1715 dean of Chichester. For his opposition to Dr. Hoadley in the Bángorian controversy he incurred the royal displeasure, and in 1717 was removed from the list of the king's chaplains. He was made bishop of Bangor in 1728, of Salisbury in 1734, and of London in 1748. His works consist principally of sermons, and were published in 5 vols. 8vo in 1830. Of his "Pastoral Letter," published after the earthquake in 1750, nearly 100,000 copies were printed.

SHERMAN. I. A central county of Nebraska, intersected by Loup fork; area, 576 sq. m.; pop. in 1875, 496. It has been recently formed, and is not included in the census of 1870. It consists mostly of prairies. **II.** An unorganized N. W. county of Kansas, bordering on Colorado; area, 900 sq. m. It is drained by affluents of the Republican river. The surface consists of undulating prairies.

SHERMAN, a city and the county seat of Grayson co., Texas, situated in a plain, 12 m. S. of Red river, 240 m. N. N. E. of Austin, and by rail 378 m. N. by W. of Galveston and 632 m. S. W. of St. Louis; pop. in 1870, 1,439, of whom 490 were colored; in 1875, estimated by local authorities at 7,000. It is at the junction of the Houston and Texas Central railroad with the Transcontinental branch of the Texas and Pacific railroad, is regularly laid out, and has many substantial brick buildings, some of them with iron and stone fronts. A court house of brick and stone, to cost about \$80,000, is in course of construction (1875). Sherman supplies several counties with merchandise, and ships large quantities of cotton, hides, &c. It contains an iron foundry, five flouring mills, a cracker factory, a tobacco factory, a soap factory, two banks, ten schools, three newspapers (one daily), and eight churches.

SHERMAN, Roger, an American statesman, born in Newton, Mass., April 19, 1721, died in New Haven, Conn., July 23, 1793. He was a shoemaker till after he was 22 years old. In 1743 he removed to New Milford, Conn., where with a brother he kept a small store. In 1745 he was appointed surveyor of lands for the county, and for several years after 1748 he

furnished the astronomical calculations for an almanac published in New York. He was admitted to the bar in 1754, was several times elected to the colonial assembly, and in 1759 was appointed judge of the court of common pleas. Having removed to New Haven in 1761, he became judge of common pleas there in 1765, and the next year an assistant or member of the upper house in the legislature (a body consisting of 12 persons), both which offices he held for about 19 years, and his judgeship till 1789, the latter portion of the time on the bench of the superior court. He was a member of the continental and the United States congress from 1774 to 1791, when he was elected United States senator. He was also a member of the governor's council of safety, and from 1784 till his death mayor of New Haven; and he was for many years treasurer of Yale college. In 1776 he was a member of the committee appointed to draft the declaration of independence, of which he was one of the signers; and during the war he performed important services on committees and boards. In 1783 he was associated with another judge in codifying the laws of Connecticut. He had been one of the committee which framed the old articles of confederation; and he was one of the most efficient members of the constitutional convention of 1787, and was chiefly instrumental in securing the ratification of the constitution by the state convention of Connecticut.

SHERMAN. **I. William Tecumseh**, an American soldier, born at Lancaster, Ohio, Feb. 8, 1820. He graduated at West Point in 1840, served in the Florida war in 1840-'42, and was at various military posts in the south till 1847, when he went to California, and was acting assistant adjutant general there till 1850. He was on commissary duty at St. Louis in 1850-'52, and at New Orleans till Sept. 6, 1853, when he resigned. From 1853 to 1857 he was a banker in San Francisco and New York, and in 1858-'9 he practised law in Leavenworth, Kansas. He was superintendent of the Louisiana military school at Alexandria from 1859 to January, 1861, when he went to St. Louis. On May 14, 1861, he was reappointed in the army with the rank of colonel, and on the 17th was made brigadier general of volunteers; and he commanded a brigade in the first battle of Bull Run (July 21). In October he was appointed to the command of the department of the Cumberland, but afterward took charge of a camp of instruction at St. Louis till February, 1862, when he was placed in command of the district of Paducah, Ky. He commanded a division in the Tennessee and Mississippi campaign, was in the battle of Shiloh, April 6, 7, where he was wounded, was in the advance upon and siege of Corinth, April 15 to May 30, and was made major general of volunteers May 1. He commanded the hastily organized expedition which attempted to capture Vicksburg, Dec. 27-29. In 1863, in command of the

15th army corps, he led the expedition which carried Arkansas Post by assault, Jan. 11, and till July 3 was actively engaged in the siege of Vicksburg. He was made brigadier general in the regular army, his commission dating from July 4, and during the summer and autumn was engaged in various operations in Mississippi and Tennessee. He commanded the left wing of the army at Chattanooga, Nov. 23-25, and at the beginning of December compelled Gen. Longstreet to raise the siege of Knoxville. In February, 1864, with 20,000 men, he marched to Meridian, Miss., and broke up the railroads centring there. He held the command of the department and army of the Tennessee till March 12, when he took that of the military division of the Mississippi, composed of the departments of Ohio, Cumberland, Tennessee, and Arkansas. Having organized at Chattanooga an army of 100,000 men, he invaded Georgia, engaging the confederate forces under Gen. J. E. Johnston, whom he forced to evacuate Dalton (May 12), at Resaca (15), Cassville (19), Dallas (25-28), and afterward almost daily till the protracted operations about Kenesaw mountain, near Marietta (June 20-July 2), which involved a severe repulse (June 27). He occupied Marietta on July 3, and after several other engagements repeatedly defeated Gen. Hood, Johnston's successor in command, before Atlanta, the severest battle being fought on July 22, and began the siege of that city. On Aug. 12 he was made a major general in the regular army. The battle of Jonesboro was fought Aug. 31. In the night of Sept. 1 Atlanta was evacuated by Hood, and Gen. Sherman occupied the city till the middle of November, when he began his famous march to the sea. He reached Savannah Dec. 13, stormed and captured Fort McAllister, and on the 21st received the surrender of the city. With the Savannah river as his base he marched into the Carolinas, and occupied Columbia, S. C., on Feb. 17. He captured Cheraw on March 3, and Fayetteville, N. C., on the 12th. On the 16th he fought the battle of Averysboro, and on the 19th, 20th, and 21st that of Bentonville, and on the 23d entered Goldsboro. On April 13 he occupied Raleigh, and on the 26th the confederate army under Gen. J. E. Johnston surrendered at Durham Station, N. C., upon terms which were rejected by the government. Sherman's advance to Richmond and Washington, from April 28 to May 24, ended his southern marches of more than 2,600 m. On June 27 he was appointed to the command of the military division of the Mississippi, comprising the departments of the Ohio, Missouri, and Arkansas, with headquarters at St. Louis. On July 25, 1866, he succeeded Gen. Grant as lieutenant general, and on Aug. 11 took command of the division of the Missouri. In November and December he was employed on a special mission in Mexico. He was made general on the vacation of that grade by President Grant,

March 4, 1869. In November, 1871, he obtained leave of absence for a year, during which he travelled in Europe and the East, and was everywhere received with great distinction. On his return he took up his residence in Washington as commander-in-chief of the army, but in October, 1874, removed his headquarters to St. Louis. He has published "Memoirs of General W. T. Sherman, by Himself" (2 vols. 8vo, New York, 1875). **II. John**, an American statesman, brother of the preceding, born at Lancaster, Ohio, May 10, 1823. He was admitted to the bar in 1844, and in 1854 was elected a member of the 34th congress, and was reelected to the 35th and 36th congresses. He was the republican candidate for speaker in the 36th congress, and after a protracted contest failed of election by one or two votes, and was made chairman of the committee of ways and means. In 1860 he was again elected to congress, but in 1861 was chosen a United States senator from Ohio, to which office he was reelected in 1867 and in 1873. He has been from his first entry into the senate chairman of the committee on finance.

SHERRY. See SPAIN, WINES OF.

SHERWOOD, Mary Martha, an English authoress, born at Stanford, Worcestershire, July 6, 1775, died at Twickenham, near London, Sept. 30, 1851. She was a daughter of the Rev. George Butt. Her earliest work, "The Traditions," was published when she was 17 years old; and in her 20th year she published "Margarita," a fiction. "Susan Grey," "The Beautiful Estelle," and some smaller works appeared prior to 1800. In 1803 she married her cousin Henry Sherwood, a captain in the army, and in 1804 accompanied him to India, where she instructed the orphan children of his regiment. In 1818 Capt. Sherwood returned to England with his family, and in 1821 retired on half pay, settling at Wickwar, Gloucestershire, where they resided for the next 27 years. Mrs. Sherwood's works amount to 90 volumes, including "Chronology of Ancient History" and "Dictionary of Scripture Types." Her best known works are "Little Henry and his Bearer," "History of Henry Milner" (3 vols.), "Ermina" (3 vols.), "Roxobel, a Novel" (3 vols.), and "The Lady of the Manor" (7 vols.). Her memoir, mainly an autobiography, has been published by her daughter.

SHETLAND ISLANDS, or *Zetland*, a group in the Atlantic ocean, forming the northernmost part of Great Britain, mainly extending from lat. 59° 50' to 60° 50' N., and from lon. 0° 45' to 1° 45' W.; area, about 450 sq. m.; pop. in 1871, 31,608. There are about 100 islands, not more than one fourth of which are inhabited. The largest island is Mainland, which contains about three fifths of the total area and two thirds of the population; and those next in importance are Foula or Foul (the westernmost), Papa-Stour, Muckle Roe, Whalsey, Yell, Bressa, Fetlar, Unst, E. and W. Burra, Fair (the southernmost), and the three Skerries.

Lerwick, on the E. coast of Mainland, is the capital. The coasts are generally bold and precipitous; they vary in height from 500 to 1,200 ft. above the sea, and are indented with numerous deep landlocked bays and by long narrow arms of the sea called *voes*. The interior is not generally much elevated above the coasts, the highest summit in the group, in the N. part of Mainland, rising 1,476 ft. above the sea. The surface is mostly rugged, or covered with moss, and the only tolerably fertile soil is in a few of the valleys and in the neighborhood of some of the bays. The geological formation consists of sandstone, gneiss, blue limestone, clay and mica slate, and granite. Copper has been discovered on one of the islands, and chromate of iron is exported from Unst. The climate is not remarkably cold, but there is much wet and tempestuous weather, and fogs are frequent. In winter it is dark and dreary, but about midsummer the sun scarcely disappears below the horizon. Very little of the soil is arable. The principal crops are oats, barley, potatoes, and turnips. The live stock on the group are very diminutive; and small ponies, or shelties, are bred wild on the heaths and pastures and exported in great numbers. About 4,000 of the inhabitants are employed in fishing. Herring, cod, ling, and tusk are the principal kinds caught. The fishing season lasts about three months during summer. The only important manufactures are hosiery, straw plaiting, and the preparation of kelp; but the two latter have fallen off greatly of late years. The exports are fish, oil, cattle, horses, eggs, and woollen articles knit by hand. The value of exports is £100,000 a year. Places of worship are numerous, and nearly all the inhabitants can read and write. The people are small, active, and hardy.—Shetland is supposed to be the Thule of the ancients, and the first people known to have inhabited the islands were of Scandinavian origin. The present inhabitants are of their race. About 875 Harold Harfager reduced all the northern and western islands to his authority. Sigurd became earl of Orkney, Caithness, and Shetland; but the authority of the earls was little felt in the last, as they had no jurisdiction in civil affairs, and were merely military protectors or leaders. When James III. of Scotland married the princess Margaret of Denmark in 1469, he received as a pledge for the payment of her dowry the Orkney and Shetland islands, and they were never redeemed. The Shetland islands with the Orkneys form a district which returns one member to parliament.

SHEW BREAD (Heb. *le'hem hapanim*), the name of 12 unleavened loaves placed upon a table in the outer compartment of the Jewish sanctuary. Though the number 12 represented the 12 tribes, it was not diminished after the secession of 10 of the tribes from the Mosaic worship, probably because the covenant with the whole people was regarded as eternally

binding. The loaves were placed in two piles, one above another, and were changed every sabbath day by the priests. The removed bread became the property of the priests, who alone had a right to eat of it, and only in the holy place. But in cases of emergency they incurred no blame by giving it to persons who were in a state of ceremonial purity, as in the instance of David and his men (1 Sam. xxi.).

SHIAHS, Sheeahs, or Shiites (Ar. *shia*, a faction), a sect of Mohammedans, who believe that Ali, the son-in-law of Mohammed, was by right entitled to be his immediate successor. The proper name of the sect is *Shiat Ali*, or Ali's party. After the death of the prophet the party that supported Ali's rivals, Abubekr, Omar, and Othman, successively effected their elevation to the caliphate before him, and he did not attain that office till 23 years after the death of Mohammed. The Shiah consisted mainly of the Persian portion of the early adherents of Islam. They entertained the most exaggerated notions concerning Ali, and even during his lifetime propounded doctrines assigning to him a certain participation in the nature and attributes of God, and placing him above Mohammed. The Shiah reject such of the traditions of Islam as relate to the first three caliphs or any other enemies of Ali, and they accept certain traditions which are rejected by the Sunnis, or orthodox Mohammedans. To the common formula of faith, "There is no God but Allah, and Mohammed is his prophet," they add, "Ali is the vicar of God." The Shiah doctrines made rapid progress, and in the early centuries of Islam repeatedly attained to power (see CALIPH); and at present they form the majority of the Persian and Hindoo Mohammedans.

SHIAWASSEE, a central county of Michigan, intersected by Shiawassee river, a head stream of the Saginaw; area, 576 sq. m.; pop. in 1874, 21,773. The surface is undulating and the soil fertile; timber is abundant, and bituminous coal is found. It is traversed by the Detroit and Milwaukee railroad, and the Jackson, Lansing, and Saginaw division of the Michigan Central. The chief productions in 1870 were 484,587 bushels of wheat, 262,861 of Indian corn, 202,510 of oats, 17,341 of barley, 240,162 of potatoes, 32,464 tons of hay, 192,612 lbs. of wool, 491,606 of butter, and 32,999 of maple sugar. There were 4,718 horses, 5,864 milch cows, 1,480 working oxen, 6,142 other cattle, 45,536 sheep, and 8,399 swine; 4 manufactories of furniture, 7 of iron castings, 2 tanneries, 10 saw mills, 6 flour mills, and 1 woollen mill. Capital, Corunna.

SHIELD (Ger. *Schild*), a piece of defensive armor, which before the invention of gunpowder was in almost universal use, but is now employed chiefly by barbarous races. It was sometimes called also buckler and target. The shield of the ancients from the earliest times was a framework of twisted osiers or light wood, over which one or more thicknesses of

ox hide and sometimes ornamental or defensive metal work were fastened; and those described by Homer covered the body from the face to the knee. Shields were carried on the

FIG. 1.—1. Scutum, from Trajan's Column. 2. Clipeus, from a Greek Vase.

left arm, and were of various shapes and sizes. The shield called by the Romans *clipeus* was large and round, having sometimes a projection in the centre of the exterior, called the *umbo*, which frequently terminated in a spike. The *scutum* of the Roman legionary soldiers was oblong and rectangular, and was generally 4 ft. high by 2½ ft. wide. The *parma*, a smaller round framework of iron covered with hides, was used by light troops; the *pelta*, which was lighter still and sometimes elliptical, but oftener truncated at the top with one or more semicircular indentations, was introduced among the Greeks by Iphicrates, and the troops armed with it were called *peltastæ*. The *cetra* was a small round target, borne by many ancient races, and probably identical with that formerly used by the Scottish highlanders. In time of peace the Greeks hung their shields in the temples, removing the handles to render them unserviceable in case of a popular outbreak. The Roman soldiers inscribed their names upon their shields, and men of family emblazoned them with devices illustrating the heroic feats of their ancestors,

FIG. 2.—1. 2. Amazons with the Pelta, from a marble bass relief. 3. Parma, from a terra cotta bass relief.

and sometimes with their own portraits, a practice to which may be ascribed the modern use of armorial bearings. To lose a shield in battle, or to return without it, was a mark

of cowardice. In the middle ages the knights and men-at-arms, being clothed in complete mail, had less need of a shield, and it fell into gradual disuse. The Norman shield until the middle of the 12th century was long and of the form called kite or pear-shaped; but subsequently it became smaller, and as a vehicle for bearing heraldic devices assumed a variety of shapes which have been preserved to the present day. (See ARMOR, and HERALDRY.)

SHIELDS, North and South, two towns of England, situated respectively in the counties of Northumberland and Durham, on the N. and S. banks of the river Tyne, near its mouth in the North sea, 6 m. below Newcastle, and 250 m. N. N. W. of London; pop. of North Shields in 1871, 8,619; of South Shields, 45,336. The manufactures of both consist principally of articles used for nautical purposes, and of glass, pottery, and alum. Ship building, once extensively carried on, has much declined, and is now chiefly confined to repairing, for which there are large docks. The entrance to the Tyne is difficult, but there are two lighthouses, one 123 and the other 77 ft. above the sea. There is an extensive stone pier at the mouth of the harbor. The name Shields is derived from the *sheels*, or sheds, in which the fishermen of the Tyne formerly lived. Interesting Roman remains were discovered at South Shields in 1875.

SHITES. See SHIAHS.

SHIKARPOOR, a town of British India, in the province of Sind, 15 m. W. of Sukkur on the Indus, on the route by the Bolan pass between Hindostan and Afghanistan; pop. about 30,000, one third Mohammedans. It stands on a low plain abounding with fruit trees, and inundated by the river at certain seasons. The place is of considerable commercial importance, and fine cotton goods are manufactured.

SHILLING, an English silver coin equivalent to 12 pence sterling, or $\frac{1}{20}$ of a pound. In reducing English money of account to United States money, a shilling is equivalent to 24.3325 cts., or, within the 1200th part of a cent, to 24 $\frac{1}{2}$ cts. The value of the coin as compared with the United States silver trade dollar, according to the proclamation of the secretary of the treasury of Jan. 1, 1875, is 21.4365 cts., or, within less than the 125th part of a cent, to 21 $\frac{1}{2}$ cts.—Many of the states while colonies had issued bills of credit which had depreciated in different degrees in the different colonies. Thus in New England currency (used also in Virginia, Kentucky, Tennessee, Indiana, Illinois, Missouri, Mississippi, Alabama, and Florida), after the adoption of the decimal system, the pound in paper money was worth only \$3.333, and the shilling 16 $\frac{2}{3}$ cts., or 6s. to \$1; in New York currency (also in North Carolina, Ohio, and Michigan) the pound was worth \$2 50, and the shilling 12 $\frac{1}{2}$ cts., or 8s. to \$1; in Pennsylvania currency (also in New Jersey, Delaware, and Maryland) the pound was worth \$2 70, and the shilling

13 $\frac{1}{2}$ cts., or 7s. 6d. to \$1; and in Georgia currency (also in South Carolina), the pound was worth \$4 20 $\frac{1}{2}$, and the shilling 21 $\frac{1}{2}$ cts., or 4s. 8d. to \$1. In many parts of the country these denominations continued to be used long after they ceased to be represented by actual money, and the reckoning by shillings and pence is not yet entirely abandoned. In Canada the shilling was formerly reckoned at 20 cts., or 5s. to \$1; but since the introduction of decimal currency in 1871, 4s. 2d. make a dollar.

SHILOH (Heb., rest, peace), a town of ancient Palestine, in the division of Ephraim, on a high mountain N. of Bethel. It was the seat of the ark of the covenant from the last days of Joshua to the time of Eli. An annual "feast of the Lord" was observed at Shiloh, and one of these celebrations was made an opportunity for the remnants of the defeated Benjamites to supply themselves with wives, by lying in ambush in the vineyards and seizing some hundreds of the dancing women. After the carrying off of the ark by the Philistines, at the close of Eli's life, Shiloh sank into total insignificance. Its site is now identified with Seilun, a small place with some Roman remains, 20 m. N. of Jerusalem.—The words in Gen. xlix. 10, which are rendered in the authorized English version "until Shiloh come," and are by Christian theologians referred to Christ as prince of peace, are explained by Jewish writers as meaning "until he (Judah) come to Shiloh," and by Vater, Gesenius, and other critics translated "until rest come."

SHILOH, a locality, so called from a church situated there, near Pittsburgh Landing, on the Tennessee river, in Hardin co., Tenn., where a battle was fought, April 6, 7, 1862, between the Union forces under Gen. Grant and the confederates under Gens. A. S. Johnston and Beauregard. The battle is sometimes called that of Pittsburgh Landing. After the evacuation of Nashville, the confederate forces in the west were concentrated near Corinth, Miss., while Grant was preparing to move so as to cut off their communications in western Tennessee. On April 1, with about 32,000 men, he reached Pittsburgh Landing, where he was to be joined by Gen. Buell. Johnston, who had about 45,000 men, moved from Corinth and attacked Grant on the morning of the 6th. The attack fell first upon the divisions of W. T. Sherman and Prentiss, both of which were driven back, three regiments of the latter being captured and the whole army forced back almost to the landing. In the afternoon Buell's advance appeared on the opposite bank, and a single division crossed while the battle was going on. Gen. Johnston was mortally wounded, and the command devolved upon Beauregard, who assailed the Union centre and left, on which most of the artillery had been concentrated, and which were also covered by two gunboats. The attack was repelled, and at night a bombardment was opened, which compelled the confederates to retire a little.

The remainder of Buell's command crossed during the night, raising the Union force to about 45,000. Grant opened the action early on the morning of the 7th, by an artillery fire, before which the confederates fell back. This was followed by a general assault, which was obstinately resisted. The action continued till 4 P. M., when the confederates retreated. The Union loss, as officially reported, was 1,700 killed, 7,495 wounded, and 3,022 prisoners; in all, 12,217. The confederate loss, as reported by Beauregard, was 1,728 killed, 8,012 wounded, and 959 missing; in all, 10,699. (See CORINTH.)

SHIMONOSEKI, a seaport of Japan, in the province of Nagato (Choshu), on the S. W. point of the main island; pop. about 10,000. It commands the strait of Shimonoseki, which connects the Inland sea and the sea of Japan. The town consists chiefly of one long street. A famous naval battle between the fleets of the Taira and Minamoto families, in which 1,200 junks were engaged, was fought near it in 1185. In 1864 the forts near Shimonoseki were bombarded and destroyed by a combined fleet of one United States, five British, three French, and four Dutch men-of-war, in retaliation for the act of the daimio of Choshu in firing on the vessels of those nations while they were passing through the strait. Besides \$420,000 demanded as a compensation for injuries, the Japanese government was obliged to pay an indemnity of \$3,000,000, of which the United States received \$750,000. In 1873 Shimonoseki was nearly destroyed by fire.

SHINER. See DACE.

SHINKING, or **Liaotung**, a province of southern Manchouria, sometimes included in China proper, bounded N. W. and W. by Mongolia, from which it is separated by a palisade barrier, E. by Corea, S. by the bay of Corea and the gulf of Liaotung, and S. W. by the great wall; pop. according to the census of 1812, 2,167,286. It is mountainous and traversed by the Liau-ho, Shin-orn, and other rivers. The products include timber, iron, coal, horses, cattle, sheep, various cereals, silk, ginseng, and rhubarb, the last two a government monopoly. The chief town is Mukden or Shinyang. (See MANTCHOORIA.)

SHINTO, or **Sinto**. See JAPAN, vol. ix., pp. 537 and 562.

SHIP, a term applied in general to all vessels navigating the sea, and in particular to sailing vessels with at least three masts carrying square sails. The masts are known as fore, main, and mizzen. The mizzen is sometimes merely fore-and-aft rigged, carrying no yard; the vessel is then known as a bark. Brigs have two masts rigged with square sails, and are generally smaller than ships; they are convenient for handling with few men, and were formerly very popular, especially in the West India trade. Hermaphrodite brigs (partly brig and partly schooner) carry on the mainmast only fore-and-aft sails; they are usually of

inferior size to full-rigged brigs. Schooners are two-masted and fore-and-aft rigged, carrying jib and flying jib, foresail and mainsail, with a gaff topsail over each of the latter, and a long square sail for the foremast, only brought out for use when the wind blows steadily from astern. The topsail schooner has a square topsail and sometimes a topgallant sail on the foremast, but the lower sail is the usual fore-and-aft foresail. These are light and easy to navigate, and excellent sea boats. Cutters used for revenue service were formerly topsail schooners; steamers have now taken their place. When it is desired to increase the capacity of schooners without increasing their draught, they are considerably lengthened, and a third mast is added to them, when they are known as three-masted schooners. Pink stern schooners, or those with high-pointed sterns, were once favorites in the cod and mackerel fishery of New England; they carried no jib, but only a foresail and mainsail. Sloops are small, generally less than 125 tons, with one mast. They carry a jib and mainsail; the latter by the great length of the mast and boom is very large. They commonly have a gaff topsail, and sometimes a square topsail, and a long square sail occasionally set. They are adapted only for rivers and comparatively smooth waters. A vessel is sometimes seen in our harbors with three masts, the foremast rigged like that of a ship and the others schooner-rigged without topsails; this is known as a barkantine.—The nations of antiquity inhabiting the shores of the Mediterranean and Red seas, and foremost among them the Phœnicians, attained considerable skill in the construction of vessels, and made long voyages. The Bible contains the description of an antediluvian vessel, Noah's ark; and it is remarkable that its proportions of length, breadth, and depth are almost precisely the same as those considered by our most eminent architects the best for combining the elements of strength, capacity, and stability. According to Gen. vi. 15, the ark was 300 cubits long, 50 cubits broad, and 30 cubits high; *i. e.*, six times the breadth for the length, and three fifths of the breadth for the depth. The ships represented upon ancient Egyptian tombs were long galleys with one mast and a large square sail, which was sometimes of linen colored or white, and sometimes of papyrus with one, and in the later periods with two yards. These were of great size and length, so that men could walk out upon the lower one, holding on by the ropes by which it was suspended from the top. The vessels were made of planks of pine, fir, or cedar, each end rising up out of the water by a long slope, well adapted in shape for easy propulsion, and were furnished with oars, upon which the war vessels were wholly dependent when in action, and all of them indeed except when the wind was favorable. The ships of war alone were decked wholly or in part, and upon the larger ones the deck was high, and in some instances

covered with structures resembling houses. According to Pliny, the Thasians were the first to construct full decks. Merchant vessels were round-bottomed for the sake of capacity. The prow was furnished with an elaborately carved image, as a boar's head, dog's head, &c., which was the symbol after which the ship was named. This symbol was termed the *insigne* (whence our word ensign), and has descended to our own times as the figurehead. Upon the stern, which rose high out of water, like that of a Chinese junk, was the image of the tutelary god with other ornamental devices. A peculiar feature in the war vessels was a projecting beak, at first made above the water line, and afterward below it, armed with pointed irons or the head of a ram, the object of which was to pierce the sides of other vessels against which it was run. This was the only part built of oak or hard wood. From want of strength in the construction of ancient vessels, and the necessity in their voyages of avoiding exposure to rough seas, they were bound around the outside with broad and thick ropes. During the gale which preceded its shipwreck the vessel which bore St. Paul, bearing the sign of Castor and Pollux, had to be "undergirded" (Acts xxvii. 17). The great ships of Ptolemy Philadelphus were provided with as many as 12 such bands, each of which was 900 ft. long. They were sometimes carried on board the vessels, to be put on when needed in rough weather. As the ships depended chiefly upon the use of oars, the arrangements for these were their most marked feature, and gave distinctive names to the several classes of vessels. (See GALLEY, and NAVY.) A Roman ship of the time of Trajan, sunk in the lake of Riccia and raised after it had lain there more than 1,300 years, was described by Leo Baptista Alberti in his book of "Architecture" (v. 12); it was built of planks of pine and cypress, daubed over with Greek pitch and calked with linen rags; the wood was in a good state of preservation; the outside was sheathed with sheet lead fastened with small copper nails.—In the middle ages navigation and ship building declined, and little is known of the vessels of that period. The expedition made by the Anglo-Saxons to England, A. D. 449, was in frail vessels, their sides made of wicker work and covered with skins. Better vessels were undoubtedly used by the Northmen in their perilous voyages. For war purposes the long low galleys of the Mediterranean gradually replaced the ancient triremes. Alfred the Great adopted them in his wars with the Northmen, and he first made the English navy unequalled. In the latter part of the 14th century the best ships were of Norman construction; in the representations of their war vessels of this period the rudder is first seen as a substitute for the great steering oars always before in use. In southern Europe the credit of first building vessels to be propelled by sails alone has generally been conceded to the Genoese. In

England many such vessels were employed as early as 1344. The use of cannon in naval warfare at the siege of Calais in the reign of Edward III. led to the enrolment of ships belonging to the crown. Ships of war had been numerous in the reign of John, but were owned by individuals; the government provided at that time for their accommodation the royal dockyards at Portsmouth. The ships of these periods were remarkable for the great height of their sides, their bulky rounded models, and the simplicity of their rig. They had no bowsprit, and seldom more than one mast; the sail was attached to a yard, which was let down to the deck when not used. They were navigated by 17 to 20 sailors only. Henry V. added to the number of English ships. His vessels were of 100 to 600 tons each, some with three, others with two masts, with short topmasts and a forestage or forecastle built up to a considerable height for the soldiers. At the mast heads were topcastles, in which men were stationed during an engagement to annoy the enemy with darts and other missiles. In the middle of the 15th century William Canynge, a famous merchant of Bristol, built many large ships, one at least of 900 tons burden, and employed altogether not less than 2,850 tons of shipping and 800 mariners for eight years. The navies of the Netherlands, Venice, Spain, and Portugal attained great importance in that century. Many of the ships being so far improved as to sail upon a wind, and the compass and astrolabe having come into use, it was now possible to engage in longer voyages and prosecute explorations in unknown seas. The discovery of America and of the passage round the cape of Good Hope were early fruits of these improvements. The Portuguese employed small vessels in their voyages of discovery, as the best adapted for explorations along unknown coasts; but the Spaniards cultivated the art of building large ones, and long maintained a superiority in this respect. The Great Harry, built in 1488, is considered to have been the first ship of the English navy as it is seen to-day, although a standing fleet was first formed under Henry VIII. She had four masts, carried courses, fore and main topsails, and topgallant sails, and had guns in broadside on two covered decks. (See NAVY.) The vessels of this period, built up with high castellated structures at each end, seem intended rather for display than for actual service, and must have been far inferior sailers to the galleasses and galleons of the Mediterranean, which had succeeded the galleys. These were of moderate height above the water, and the first had overhanging bulwarks like the guards of modern steamboats, greatly adding to the width of the decks and affording room for the rowers. The galleons, on the contrary, which depended on sails alone, were drawn in at the top to such an extent as to contract their breadth from the water line fully one half; this feature has

ever since prevailed in many European ships. Henry VIII. established the dockyards at Deptford and Chatham, and brought together from foreign countries, and especially from Italy, many skilful shipwrights and workmen. In the reign of Elizabeth the superior management of the English ships over the much larger ones of the Spaniards, with their three tiers of guns, was fully established in the contests with these vessels; and great progress was made under the encouragement of the queen in increasing and perfecting the mercantile marine. The East India company was chartered in 1600, and the increasing traffic with the distant countries of Europe and America rapidly stimulated the demand for the best vessels and called forth the ingenuity of the ship builders. Sir Walter Raleigh gave much attention to the improvement of ships, and his publications entitled "Invention of Shipping" and "Concerning the Royal Navy and Sea Service" greatly added to the general interest in the subject. The shipwrights' company, established in 1605, was incorporated in 1612, and general charge was given to the association over ship building throughout the kingdom. The first master was Phineas Pett, of a family distinguished for the principal engineers it furnished to the royal navy from about the middle of the 15th century to the end of the reign of William III. He built the Royal Prince in 1610, a ship of 114 ft. keel, 44 ft. breadth, and 1,400 tons burden, introducing the great improvement of cutting off the long projection of the prow, hitherto universally adopted, and also much of the cumbersome top hamper of the older ships. The first English three-decker was built by his son Peter Pett in 1637. She was called the Sovereign of the Seas, and had the reputation of being the best man-of-war in the world until she was accidentally burned in 1696. An account of her armament is given in NAVY. She was 232 ft. in length over all, 128 ft. length of keel, 48 ft. in breadth, and of 1,637 tons. The drawings represent her as a full-rigged ship carrying square sails altogether, topgallant sails, and royals, but no jibs or staysails. Under the bowsprit was a square sail suspended from a yard, such as is now called the spritsail. The hull was somewhat lofty in the bow and stern compared with modern ships, but still greatly reduced from the older ones. A considerable portion of the additional length above water to that of the keel was from a long triangular beak. The Constant Warwick, also built by Peter Pett in 1646, and designated a frigate, was specially intended for fast sailing; she was light, with low decks, of 85 ft. keel, 26 ft. 5 in. breadth, 13 ft. 2 in. depth, and 315 tons burden; she carried 32 guns and a crew of 140 men, and soon acquired a high reputation for her conquests among the Dutch privateers. But the Dutch ships at this time were quite equal to the English, and their navy was altogether the best in Europe, the result of their

continual wars with Spain. The merchant vessels of England were superior in sea-going qualities to those of the royal navy, and during the wars with France and Spain they boldly continued their trading voyages, two or three of them usually sailing in company. During the 18th century the French attained a decided superiority in the size and models of their ships, and the Spaniards readily adopted the improvements of the French. Their largest vessels were two-deckers only until after 1763, and their largest armaments were of 84 guns. In this respect they were inferior to the English three-deckers carrying 100 guns; but in 1768 the French adopted the English system, and built ships of 110 and 120 guns, and of 196 ft. length by 50 ft. breadth and 25 ft. depth of hold, while the English in some instances copied the lines of the French ships that fell into their hands. But it is admitted even by the English themselves that their system of ship building received no aid from the applications of science, while the French availed themselves of the highest mathematical talent as well as of practical experience and skill. To the latter and to the Spaniards also is due the credit of the important improvements made in ship building in modern times up to the present century; and yet in the United States, where the same course has been pursued as in England, of seeking aid only from experience and natural talent, the highest success has since been attained in designing the most perfect models for the special purposes required. The American ship builders were the first to entirely abandon the cherished features of the European models, as the high poop and inflected topside. Their frigates proved their superiority to all other vessels of war in actual service, and before the introduction of steam their Liverpool packet ships were the finest vessels afloat. Their fore-and-aft rigged vessels, less known abroad than the larger ships, were still more remarkable for originality and perfect success in their designs. The river sloops and coasting schooners were peculiarly American. The schooners of the Chesapeake were especially famous under the name of Baltimore clippers. Broad of beam before the centre but above the water line, sharp in the bow, deep aft, long and low, they presented admirable forms for capacity, for stability to sustain a large amount of canvas, for great speed, and for holding their course on a wind with little drifting to leeward. The masts were long and slender, the sails unusually large for vessels of their size, and of so true cut and perfect set that no portion of the propelling effect of the breeze that reached them was wasted. Close-hauled, they drew well with the vessel running within 40° or 45° of the wind, while the best equipped frigate would be sharp set at 60°. The superior sailing qualities of these schooners were shown in their success as privateers and freedom from capture in the war of 1812, and

were most conclusively established when the yacht *America*, built on the same principles, carried off the prize in 1851 in competition with the English yachts that had confidently challenged the world to a trial of speed. From these schooners the step was natural to the famous clipper ships by the adoption of the square rig for larger vessels of similar model. They were called into existence by the increasing importance of the East India trade, in which speed and punctuality were more essential than mere stowage capacity, and still more by the sudden springing up of the California trade with its immense passenger traffic. In vessels of this class the voyage round Cape Horn lost its terrors, and the passage from New York to San Francisco was confidently calculated within a few days, and this at hardly half its former length. The clipper ship *Great Republic*, built by Donald McKay of East Boston, was an excellent type of this class, and was the largest, if not the fastest, merchantman ever constructed. Her capacity was about 4,000 tons, and her original dimensions were 325 ft. length, 53 ft. width, and 37 ft. depth. A peculiar feature in her model was the rising of her keel for 60 ft. forward, gradually curving into the arc of a circle as it blended with the stem. She had four masts, all provided with lightning rods. The after one, called the spanker mast, was fore-and-aft rigged, of a single spar; the others were built of hard pine, the parts doweled together, bolted and hooped over all with iron. The main yard was 120 ft. long. A single suit of her sails consisted of 15,653 yards of canvas. Even in 1851 the performances of some of the clipper ships on long voyages were far superior for days together to those of the steam vessels of that time, and on the whole run hardly inferior. In that year the *Flying Cloud* made the passage from New York to San Francisco in 89 days and 21 hours. Her greatest distance from noon to noon of any day was 374 knots (433½ statute miles), which, allowing for difference of longitude, was made in 24 h. 19 m. 4 sec., or at the rate of 17.77 m. an hour. In 1852 the *Comet* arrived in New York from San Francisco in 83 days, and the *Sovereign of the Seas* from the Sandwich islands in 82 days. The greatest distance made by the latter from noon to noon in any day (in this case 23 h. 2 m. 4 sec.) was 362 knots (419 m.), or at the rate of 17.88 m. an hour. From March 9 to March 31, from lat. 48° S. in the Pacific to 36 S. in the Atlantic, the ship made 29° of latitude and 126° of longitude, equal to 6,245 statute miles, or a daily average of 283.9 m. During 11 of these days consecutively her daily average was 354 m., and during 4 consecutive days 398½ m. Her daily average for the whole distance of 17,597 m. was 222.7 statute miles, or at the rate of over 9 m. an hour for 1,896 consecutive hours.—The two prominent features that constitute the essential improvements of modern times are the shape of the bow and the in-

creased length of the vessel. In place of the convex form noticed in the older ships in tracing the lines from the stem aft along and below the water, is now substituted a concave surface giving to the bow the shape of an elongated wedge slightly hollowed on the face, by which the waters are more easily parted and thrown aside. This wedge shape is extended even to beyond the centre of the ship, so that the broadest part, instead of being as formerly one third the distance from the bow, is now about the same proportional distance from the stern. Above the water line the old proportions may still be retained. This form of bow is not by any means altogether new, having been adopted by the Spaniards in past times and by various barbarous nations for their small craft; but its merits not being appreciated by other European nations, it was sacrificed for the sake of greater stowage, especially by the English, who were the more impelled to this course by reason of the old tonnage laws, in force up to 1836, as regards the method of measurement for regulating the dues, the increase of capacity gained in the bow not being reckoned in the estimate. Thus the round swelling bow became the established form, in the correctness of which the builders felt confirmed by the similar shape in the head of the whale and of the codfish. The hollowed lines drawn from the stem back on each side the ship were designed by Mr. Scott Russell from his observations made as far back as 1832 upon the shape of the wave set in motion, as by the influx of water from the discharging of a lock of a canal, which travels at rates corresponding to the depth, as 8 m. an hour for 5 ft. depth, 10 m. for 7 ft., 15 m. for 15 ft., 18 for 20, 20 for 30, 25 for 40, and 30 for 50. Hence he designated them wave lines, and the form of the bow they produced he called the wave form. The lines for the stern he also established by study of the refilling or replacing or following wave, as necessarily falling in cycloidal curves. Definite lengths indicate definite rates with a given power, and it would be impossible to force a ship through the water at rates much exceeding those indicated as adapted to the length of her lines without an extravagant expenditure of power. Additional length of body inserted in the centre seems to have no effect, except as it presents an increased surface for adhesion of the water. Thus the old idea that there must be a certain proportion between the length and breadth of a vessel, as that which for a long time was adopted in practice of one fourth the length for the breadth, proves to be entirely false. The speed does not appear to be affected by the shape of the vessel across her middle or her midship section, nor by differences of depth to a considerable extent. The proportion between the speed for which a ship is to be designed and the length of entrance and run, Mr. Russell states to be three fifths of the whole length for fore body

and two fifths for after body. For a speed of six statute miles an hour the length of entrance should be, according to his rule, 15·12 ft., length of run 10·8 ft.; for 8 m., 26·88 ft. for entrance and 19·2 for run; for 10 m., 42 and 30; for 15 m., 94·50 and 67·5; for 20 m., 168 and 120. The great experiments of the English in the construction of their largest steamers have been made on these principles. Before their adoption it was taught by the most experienced ship builders, and in this opinion Mr. Scott Russell was himself educated, that it was impossible to force steamboats through the water at a greater rate than 9 m. an hour. He had even seen engines of 50 horse power taken out of one of the short bluff-bow steamboats, and replaced with others of 75 horse power, with the effect of increasing her speed only about a quarter of a knot an hour. With the increased power the resistance in front was much more than proportionally increased, keeping down the speed in this instance to about the same amount. This was in accordance with the mathematical deduction of the resistance in passing through water increasing as the squares of the velocities, or nearly so, and the power necessary to impart an increased velocity varying nearly as the cube of such increased velocity. It is not strange therefore that the opinion prevailed, that if a rate of 12 or 14 m. could ever be attained in sea-going steamers against the enormous resistance, increased as it must be by the tremendous shock of opposing waves, no vessel could be strong enough to complete a voyage. Yet in the United States the fallacy of these views had been practically demonstrated in the steamboats on the Hudson river for several years before the principles of their success were recognized by the English ship builders. In 1827 these boats were making the trip from New York to Albany in 12 hours, the distance being about 145 statute miles, and the trip usually including 12 stoppings, at six of which the boats were brought to and fastened to the wharves. Several crossings of the river also added to the distance and the time over a trip direct. In 1829 the passage had been accomplished in 10½ hours, in 1831 in 10½ hours, and in 1832 in 9 h. 18 m. (See paper by William C. Redfield in "American Journal of Science," vol. xxiii., 1833.)* These boats were long and sharp, furnished with "cut-water bows," and of dimensions in some instances as follows: length 233 ft., breadth of hull at the water line 28 ft., depth of hold 10 ft., draught of water 4½ ft.; length 180 ft., breadth at the water line 28 ft.; length 220 ft., breadth 25 ft.; and length 145 ft., breadth 27 ft. In 1832 Mr. Russell demonstrated theoretically the princi-

ples upon which such speed was attainable, and in 1837 a river steamer called the *Vesper*, built on the lines he recommended, was actually run on the Thames at about 12 m. an hour.—The direction in which improvements in the construction of fast ships were to be made being thus determined by theory and practice both in England and the United States, an active rivalry sprang up between the two nations, each producing almost every year steamers of surpassing excellence. But the American government refusing to pay subsidies to steamship lines, the scale turned in favor of the English, whose resources were greater in other respects than those of the Americans. This was especially apparent when in the course of the contest it was discovered that a limit was encountered to the required elongation of the ships, from the want of strength in wooden timbers, however large and well put together, to bear the increased strain; and that resort must be had to iron plates riveted together, the suitability of which for such use was fully established by the success of the Britannia bridge. In 1855 the Cunard iron steamer *Persia* was constructed, of 360 ft. length of hull, 45 ft. breadth, and 32 ft. depth, and of capacity exceeding by 1,200 tons the largest of the other ships of the same line. The next of these grand attempts was the construction of the *Great Eastern*, in which the principle was put to an extreme test upon a length of hull of 680 ft., a breadth of 82½ ft., and a depth of 58 ft. Her lines were designed by Mr. Scott Russell in exact conformity with his theoretical wave lines. Those of the bow are 330 ft. in length, and the length of the run is 226 ft., the filling in of parallel body to afford the capacity wanted being 120 ft. This middle portion, as already remarked, is supposed to have no effect so long as the length in other respects is sufficient for attaining the required speed with the given power. In this case the power furnished could be expected to give only 15 m. an hour, and this she attained. For further account of the use of steam in navigation and the history of this application, see STEAM NAVIGATION.—The substitution of iron for wood in the construction of vessels was first made experimentally in 1821, but did not come into practical use till 1829–'30. In these years the late John Laird of Birkenhead built some iron cargo lighters at his works there, where the business of iron ship building has since been uninterruptedly continued, and upward of 400 iron vessels have been completed. In 1830–'31 the late Sir William Fairbairn built a small iron steamer at Manchester, and he afterward constructed at Millwall many steamers of the same material. In France and in the United States iron has been partially introduced into wooden ships, bars of iron being employed to great advantage for a diagonal bracing covering the inner surface of the timbers with a complete network; horizontal stringers of plate iron are also fas-

* Since the publication of the paper by Mr. Redfield still increased rates of speed have been attained by these boats, till, in October, 1860, the steamboat Daniel Drew made the trip in 6 h. 50 m., including in this five landings and several crossings involved by them; these may fairly be considered as consuming 50 minutes, thus making the rate 24 m. an hour, the highest speed ever recorded upon the water.

tened to the sides within at intervals from the deck to the keelson, which is also of iron. The beams are also made of iron, shaped like those used in house architecture, and in various other parts this metal is substituted for wood, the advantage being greater strength with less weight and the occupation of less room. Iron frames are now used exclusively in the English navy. Ships constructed wholly of iron are lighter than those of the same tonnage made of wood, and consequently can carry larger freights. Their size moreover being capable of enlargement beyond the dimensions to which wooden vessels must be limited, they admit more than the latter of profiting by the principle, that the larger the capacity the less proportional part of it need be devoted to the transportation of the fuel required, and the more may be devoted to the cargo. Iron ships are built upon a frame of ribs and longitudinal pieces, upon which the outer plates are secured by bolts and rivets passing through their overlapping edges. Lloyd's rules for iron ships will be found in "Ship Building in Iron and Steel," by E. J. Reed, p. 491. In 1858 a steamer called the *Rainbow*, of 170 tons and 130 ft. length by 16 ft. beam, intended for the Niger expedition, was built with plates of steel. These were rolled from lumps of crude steel which were exposed four hours in a close furnace to a temperature a little below the melting point; by this process the steel was made to assume a more homogeneous texture and uniform strength. Its advantage over ordinary iron plates is that equal strength to that of the latter is obtained with only half the weight. The boilers of the steamer were also made of it.—The recent important changes in ships intended for naval service are: 1, the introduction of light and swift vessels propelled by steam, carrying a few heavy guns, and able by their light draught to run into rivers and shoal waters; and 2, that of floating batteries, some account of which has been given in the article IRON-CLAD SHIPS. Since 1858 the French and English governments have vied with each other in the construction of fighting ships in which the maximum powers of offence are afforded the utmost security from hostile shot consistent with buoyancy. The contest between offence and defence is in reality coeval with the history of ship building. In the earliest sea fights protection from the missiles of the enemy was sought by placing shields, interlaced, on what now would be called the "gunwale" of war galleys. During the middle ages the same expedient was resorted to. At the siege of Tunis in 1535 the *Santa Anna*, one of the fleet of the renowned *Andrea Doria*, was plated with lead, and successfully resisted the artillery of the enemy. The light armaments of the last century often failed to penetrate the stout oak or teak sides of well built ships. Even so late as 70 years ago the ships of Nelson and Collingwood, so long under a concentrated fire as they bore down on the enemy's line at

Trafalgar, would have been completely demolished had not the powers of attack and defence been so nearly equal. (See IRON-CLAD SHIPS.)—Composite ships are designed to combine the advantages of an iron frame or hull with those of a wooden bottom sheathed with copper or zinc. As the bottoms of iron sea-going ships get so foul by the adhesion of shell fish and sea weed as to materially reduce the speed, the protection of the iron becomes a very important consideration. The bottoms of wooden vessels are protected by a sheathing of copper, which by exfoliation sheds or sloughs off such adhesions. The chlorine contained in sea water has a strong affinity for copper, forming a green chloride of copper, which is dissolved by the water, and thus the copper is wasted away. This waste, which constitutes one chief value of copper as a sheathing, can readily be prevented. Chlorine is electro-negative. If the copper sheathing were rendered electro-negative also, the chlorine would be repelled instead of attracted, and the metal would be protected from corrosion. Sir H. Davy proposed to do this by driving zinc nails into the copper. The zinc at once becomes electro-positive, attracts the chlorine to itself, and generates an electrical current which is transferred to the copper; it thus becomes the generating plate of a battery, while the copper becomes the conducting plate. But while chlorine is repelled, lime and magnesia, electro-positives, are attracted to the copper, forming an earthy coating to which shell fish and sea weed readily and firmly adhere. This explanation shows why all the patent applications for the bottoms of iron ships fail to prevent fouling. No artificial coating possessed of the essential property of exfoliation has yet been devised. As any communication, through the medium of salt water, between copper sheathing and an iron hull would generate galvanic action highly destructive to the latter, it becomes necessary to insulate the iron by applying planking to the bottom and then sheathing that; hence we have what are now commonly known as composite ships. With copper sheathing the iron must be perfectly insulated; with zinc this is not necessary, as it decomposes instead of the iron when they are in galvanic communication with each other. The English frigates *Shah* and *Inconstant* are composite. They have a double thickness of wood sheathing outside the iron skin, with copper over all, and brass stems and stern posts. A sheathing of three-inch teak is first laid fore and aft and bolted to the shell of the ship; next comes a layer of planking of the same thickness, but of lighter wood, secured with shifting butts and seams to the first by brass wood screws. The wood sheathing is calked, paid with pitch, and then coppered. The composite system will be adopted in the new monitors now (1875) in course of construction in this country.—*Ship Building*. Few if any mechanical operations demand such a variety

of considerations as the building of a ship. A hollow shell is to be constructed in which lightness and stability are the first requisites. If the vessel be a man-of-war, it is a nice point to determine her displacement, or the entire weight of the structure itself with all that she carries of spars, armament, men, supplies, &c., that from this her depth in the water may be known, and the line of her lower ports be fixed so high as not to be washed into in time of action. The form is to be specially suited for easy and rapid progress, and at the same time must be adapted to resist the severest strains, caused not merely by the weight of the structure and of its load, but by the shock of the waves, and their constantly varying figure, the effect of which is to continually change the places of support, and throw large portions of the weight first upon one point and then upon another. It has often been observed that after a vessel has left the stocks upon which she was put together, and lies upon still water, a line that had previously been drawn straight along her top side from stem to stern is deflected several inches by the settling of the ends, which is owing to a want of precision and strength in the work to meet the inequality of the weights on the different transverse sections. The effect is to separate to some extent the planks and connecting pieces at the top, and compress those in the bottom of the structure. When the ship enters rough water, she is at one moment supported at the two extremities like a bridge, and the great weight bears down the middle, threatening to bend the whole structure and produce the effect called sagging; the next instant her bow and stern hang unsupported over the great wave which bears up the ship across her centre, and the two ends tend to droop; the latter change of form is called hogging. If the ship was thus affected when first launched, it is obvious that the distortion must increase as she works in a heavy sea, and that her timbers and fastenings must be greatly weakened by the motion. In various other ways the strength of her framing is severely tried. Driven obliquely across the waves, she is lifted high upon their summits, and at any moment is dashed into the trough against the next coming swell, the force of which she receives upon her bow, side, or quarter, with a shock that quivers through every timber. When following too nearly the line of the waves, she is rolled violently from side to side, and the great weight and long purchase of the heavy yards and masts act with fearful power to strain the sides, to which they are fastened by the shrouds and stays. Again, when moving directly across the waves, each end is in turn elevated and depressed. In all these movements the force of the strain is told by the creaking of the timbers. The structure is put to still severer tests when the ship touches an uneven bottom, and the weight is supported by a few points upon a hard un-

yielding surface. Then, beaten by the waves, raised up and dashed down again by them, her frame is most perfect if she is not soon parted and broken up. Indeed, the only vessels ever known to come off from a rocky exposed coast after remaining aground for a considerable time were iron ones, as the *Great Britain*, which lay a whole winter on the coast of Ireland, and the *Vanguard*, which was for several days on a rocky beach. The strength of ships, like that of roofs and bridges of long span, depends on the skilful arrangement and fitting of the timbers, so that they shall take the strains they are to meet to the best advantage, as well as on the bolts and fastenings by which they are held in their places. The keel is the foundation or backbone upon which the whole structure is built up. It receives the great upright timbers of the stem and stern, and those called floor timbers that support the ribs, which give form to the sides. The deck beams at different stages, securely fastened at their ends to opposite ribs, hold these together against any spread of the sides or lateral hogging, and also act as struts to prevent collapsing of the sides. Curvature on the length of the ship is guarded against by the planking on the ribs and that of the decks, the planks being laid longitudinally and strongly bolted down to the timbers. In northern Europe since the middle of the last century a system of trussing has been introduced for greater security in this respect. Three parallel rows of pillars were set up extending from one end of the ship to the other, one row on the keelson, and one each side on timbers laid for the purpose and bolted to the ribs. On the top of the pillars of each row and directly under the lower deck was secured a longitudinal timber like an architrave; and diagonal braces extended from the top of one pillar to the foot of the next in the same row. By such arrangement the stiffness was materially increased, but at the expense of stowage room, and the trussing was not altogether secure of remaining in place in the violent movements of the ship. A much superior method was introduced in 1810 by Sir Robert Seppings, surveyor of the navy, which is known as the diagonal bracing. This was formed of a system of timbers crossing the ribs on the inside of the ship at angles of about 45°, and braced by diagonals or struts. This framing started below at the keelson or horizontal timbers at its side, to which it was strapped down, and terminated above under the horizontal shelf which supported the ends of the cross beams under the lower deck. The shelf was thus braced up and supported; and in large ships the second horizontal shelf was likewise sustained by a continuation of the diagonal bracing above the lower deck. These shelves secured to the sides of the ship are always provided for the support of the deck beams, and serve themselves to stiffen the structure in their action like internal hoops. In place of this method

iron plates or straps are now commonly employed in all important wooden ships for diagonal bracing. Diagonal braces are from $\frac{3}{4}$ to $\frac{1}{2}$ in. thick, and from 3 in. to 5 in. wide, laid at an angle of 45° with the keel. There are two tiers, which cross each other at right angles, and end on a belt of iron above the spar deck, called a head strap, somewhat larger than the diagonal straps. Straps are put either inside or outside of the frame in the merchant service; in the United States navy it is customary to put them inside. As wooden vessels now are not so deep in proportion to their length as in former years, the strength secured by this system of iron strapping is indispensable.—In designing a ship, the old plan, after deciding on her tonnage, is to determine the proper midship section for the proposed capacity, with due reference to the desired speed, degree of stability, &c. The next thing is to plan the horizontal section called the load water section, and then prepare the drawing on a scale of a quarter of an inch to the foot. The three principal draughts are known as the sheer plan, the half breadth plan, and the body plan. The first is a vertical section extending the whole length of the ship, and presenting her full depth, the inclination of her stem and stern, her masts, ports, water lines, and generally whatever belongs to the side of the ship. The water lines are drawn straight and parallel, numbered from stem to stern. The half breadth plan is a horizontal section of half the ship divided lengthwise as seen from above. The several water lines, numbered as in the sheer plan, are dotted in, or drawn in blue ink, and designate the width and horizontal curves of the hull at the different levels. The body plan is a midship section, representing the height and breadth of this portion of the ship; it is divided vertically into halves, that to the left showing the curves and arrangement of the timbers toward the stern, and the other those toward the bow; the heights of the several water lines are also indicated. Instead of these plans, the American ship builder has generally substituted a half model of the vessel built up of thin strips of wood laid horizontally upon each other. These strips represent the parallel water lines, and can be taken apart for any alteration of the plan, or for laying off from them the full size lines upon the floor of the moulding loft. This loft is a large room specially devoted to the preparation of the designs and patterns from which all the timbers are to be shaped. The designs being drawn upon the floor, the plank patterns or moulds are obtained from them, which are of the exact dimensions of one face of the timber, and are furnished with marks that designate the other dimensions. The ship yard is situated by the edge of the water, and sufficiently elevated to secure a proper slope for the completed vessel to slide down the ways. At a convenient distance out of the reach of the tide a row of blocks, 4

ft. or more apart and 3 ft. high, is set in the ground, extending back from the water the proposed length of the ship, and their flat upper surface sloping toward it about 3° from the horizontal. On these blocks the timbers which make the keel are laid, being nicely fitted together by scarfing and secured by bolts. In Europe elm is preferred for the keel, being tough, holding the fastenings well, and long remaining sound under water; but in the United States live oak is commonly used. The latter is the most valuable native timber employed in ship building; but white oak of second growth obtained near the coast in New England is also excellent, and far superior to the same timber brought from the interior. Locust and cedar are strong and durable, and hackmatack is valuable for knees. Chestnut is employed to some extent, and white and yellow pine largely, the latter being the best for decks. It is recommended that the trees be killed by girdling in the beginning of the winter when the sap is down, and left to dry and harden before they are felled. After this the timber should be stored in a dry airy place to season. False keels or shoes are from 4 to 6 in. thick, and fastened to the lower side of the main keel with spikes or short bolts, after the frame bolts, which pass through the frame and the main keel, are clinched. The chief object of the false keel is to save the main keel from injury in case the ship should strike the bottom. Ships are generally built with the stern nearest the water, although sometimes it is more convenient to build and launch sidewise. On the fore end of the keel is erected the stem, on the after end the stern post, with its lower end tenoned into the keel. The frames which cross the keel are formed of floor timbers and futtocks. They are put together while in a horizontal position, with the floor timbers lying across the keel. When all are calked and bolted together the whole frame is canted up by proper purchases, cross pawls preventing it from spreading. The frames thus crossing the keel are called square frames, as they are placed at right angles to the keel; forward and abaft of the square frames are the "cants" or cant frames, so called because they cant toward the round of the bow or stern. The keelson is a longitudinal timber parallel to the keel, and occupying a place on the inside of the frames corresponding to that of the keel on the outside. The spaces between the frames are generally filled in solid with white or live oak timber. The keelson is built in one or more pieces varying with the size of the vessel. After the frames are erected they are regulated so as to stand square with the keel longitudinally and level transversely. Heavy rib bands are attached to the frames on the outside, and secured by heavy shores. The inside of the ship is then prepared for strapping, ceiling, placing and kneeing of beams, laying decks, &c. The outside of the frame is covered with plank

nearly parallel in width and of various thicknesses; the plank or wales above water are the thickest, being in a large ship from $5\frac{1}{2}$ to $7\frac{1}{2}$ in., the bottom plank from $3\frac{1}{4}$ to $4\frac{1}{2}$ in. The lowest tier or strake of planks outside, known as the "garboard strake," meets the keel along an angular recess called a rabbet, which is cut into its side for the purpose of affording to these planks a tight fit along their lower edge. The keel is thus interlocked along its whole line between the planks each side of it. In large ships this lower tier is sometimes of timbers rather than of planks. The other planks are from 3 to 7 in. thick. To obtain the curves required for the planks to fit the bends, these are steamed in tanks, and then are brought into shape by bending them with screws and levers between fixed supports. The inner planking, known as the ceiling, begins near the keelson with what is called the limber strake, extending along the whole bottom of the hold, one on each side the keelson. The narrow space between is for a gutter to collect the drainage water, for delivering it to the pumps. Such a passage is called a limber. The strakes over the heads and heels of the timbers are thicker than elsewhere, to give additional security against their ends being pressed in. As the planking is carried up, the projecting pieces called shelves are set in their places and strongly secured, the deck beams are laid upon them, and the ends of these are fastened with wooden or iron knees of great strength. Under the middle of the beams are placed pillars, starting from the keelson; these prevent the settling of the beams, which are arched upward, and their consequent thrusting outward of the sides instead of tying them to a fixed width. As in the rolling of the ship a powerful strain is exerted to lift the ends of the beams, this is also guarded against by another projecting timber set in the planking directly over the beams. This is called the waterway, and is secured by vertical bolts extending through the beam and shelf, and by horizontal bolts that pass through the frame and outer planking. The planks are fastened to the timbers with treenails (*i. e.*, pins of locust) or with bolts or spikes. Treenails have sometimes been made with a thread cut round them and a square head by which they are seized and screwed into the holes. For the decks yellow pine planks are commonly used, except along the sides of the ship, where a strake of hard wood thicker than the rest of the planks, called the binding strake, is laid for a waterway. In laying the deck planks attention should always be directed not merely to their use as a covering, but also to their action as longitudinal ties for the frame. In some instances decks have been laid diagonally from one side to the other, obviously involving a loss of strength; ships have also been built with three layers of planks for the decks and outer covering, two diagonal layers crossing each other, and a third upper layer running

longitudinally. At the ends of the ship the shelf pieces, waterway planks, and strakes are secured to the beams, and crutches attached to the stern post and to the timbers called breast hooks, that spread out from the stem. The openings left in the deck for hatch and ladder ways necessarily weaken it somewhat, though they are provided with stout framing secured to the beams. The holes for the masts are large enough to receive wedges all around of 3 to 6 in. thickness. For supporting the masts blocks called steps are fastened to the keelson, or for light masts to one of the beams, and into a cavity of these blocks the heel of the mast is set. A great variety of work still remains for the ship carpenter to complete before he can give place to the calker, whose office it is to make the seams of the deck and outer planking water-tight. The bulwarks have to be finished, the pumps placed, the capstan or windlass for raising the anchor, the catheads for suspending it over the sides, &c. Calking consists in driving threads of oakum, rolled up in the hand, into the seams between the planks; and that it may reach to the bottom and make the seam perfectly tight, the planks should be bevelled on the outer edge to present an opening gradually closing toward the bottom. The width of the opening is sometimes increased by driving in an iron wedge-shaped tool, and the oakum is then crowded in with great force by the calking iron. When the seams are filled they are payed over with melted pitch; but a much better material sometimes used is the marine glue, prepared from shell lac and caoutchouc. (See GLUE.) The rudder is sometimes hung before launching, but more frequently afterward. This is made of timbers as thick as the stern post, up and down which it extends, and to which it is suspended by pintals on the rudder fitting into braces on the stern post. The head of the rudder passes up through the stern above the deck, and to this a handle called a tiller is fastened for turning the rudder.—The ship being ready for the launch, two parallel lines of heavy timbers are laid along her length, one on each side, and continued down into the water till sufficient depth is reached for the vessel to float. The fall of the water at low tide affords the opportunity for doing this. The slope of this track, or of the "ways," is about seven eighths of an inch to the foot for large vessels; small vessels require a little more inclination. The timbers are held together by others underneath crossing them, and the frame is kept down by being loaded with stones; this at least is the practice where the sliding ways are not permanent. The top of each timber is well covered with melted tallow, and upon this when cold is added soft soap or oil. On the top along the outer edge a ribbon of hard wood full 5 in. square is fastened down, and braced by a succession of shores extending back on each side against some solid support in the ground; the object of this ribbon is to prevent

any outward deviation of the upper timbers that make the cradle in which the ship is held as the whole slides down together. This second system is loosely piled up under the ship, the lowest portion being timbers smooth and well greased on the under side and laid directly on the ways. Between these timbers, called the bilgeways, and the bottom of the ship over them, the space is filled in partly with blocks of timber and planks, and toward the bow and stern by short shores, called poppets, set up from the bilgeways to the bottom of the ship, their steadiness being secured by stout planks temporarily fastened along the bottom against the heads of the poppets. Near the stem and stern chains are passed across to hold the cradle together. To the front of the timbers of the cradle are fastened ropes that are passed over the bow into the ship, and are intended to hold these when they float away from under the vessel. To bring the weight of the ship upon the cradle after this is fitted under it, long wedges are driven in over the bilgeways from one or both sides of each of them. The shores at the sides of the ship, which had heretofore aided to sustain her, and the blocks beneath the keel, which took the chief portion of the weight, may now be removed, with the exception of a few of the latter under the forward part of the vessel. All this preparatory work is done on the rise of the tide; and when this is at about its height, and two short shores, called dog shores, have been placed, one on each side the vessel, to brace from the ways as a fixed point forward against the bilgeways, and thus hold the cradle with its load from sliding too soon, the fore blocks are split up with wedges and drawn out, letting the whole weight settle down on the ways. At an order the dog shores are knocked down, and the structure begins to move, at first slowly and then with rapidly increasing velocity. In rivers and contracted places the course of the vessel is checked by a hawser made fast on shore, or she is brought up by letting go an anchor. The French have long practised launching vessels without side ways, the weight being entirely supported upon a sliding plank fitted under the keel. A strip of timber is fastened along under the bilge on each side, and a few timbers are laid up in the usual place of the ways, reaching within about half an inch of these strips. It is not expected that they will come in contact except in case of the vessel heeling, when they will serve to prevent her falling over. After the launch the vessel is conducted to the wharf to receive her spars, rigging, and machinery, if a steam vessel, and interior finish; or she may be taken into the dry dock to be sheathed. It is important to protect the bottom of a vessel with a metallic covering, as without this it soon collects an incrustation of marine vegetable and animal bodies, which seriously interferes with their progress through the water, and the timbers are liable to be attacked by

the ship worm. Sheet lead was used in ancient times, and sheet copper was first applied to the ships of the royal navy in 1783. The great expense incurred in suits of copper, which need frequent replacing, is much reduced by the use of Muntz's yellow metal, a combination of copper and zinc described in the article BRASS. The metallic sheets are of different thicknesses for surfaces more or less exposed, the weights being 32, 28, 18, and 16 oz. to the square foot. The thickest sheets are used for the bow and about the load water line. The size of the sheets is 4 ft. by 14 in., and a 120-gun ship would require of them 4,444. They are fastened with copper nails, and are laid so that each sheet laps upon the edge of the next one to it behind and below.—*Masts and Rigging.* The spars include the masts, yards, booms, and gaffs, used to support the rigging and sails. The masts of the smaller vessels are single sticks of pine timber well rounded and with a gentle taper. For large ships it is necessary, on account of the size of the masts, to construct them of a central stick of a number of sides, with longitudinal pieces closely fitted and securely attached to them and then hooped with iron; these are called made masts, and are stronger than the single sticks of the same size. Hollow masts of plate iron are in use, particularly for iron vessels. Rules for the length of the mainmast of a ship have been half the sum of the length of the load water line and the main breadth of the vessel, and also twice the breadth added to the depth. About the head of each of the lower masts are framed timbers making a horizontal scaffolding or platform, which is known as the top. On large ships it is railed around, and on vessels of war it used to be the custom to station men in it during an engagement armed with muskets. Upon the rounded front edge of the top stands the topmast, secured in part by passing above through a strong iron-bound flat block set horizontally upon the upper extremity of the lower mast and called a cap. The topmast is about three fifths the length of the lower mast; and above it succeed in like manner the topgallant mast and royal mast; and in seas where the prevailing winds are light and are felt more aloft, still another mast is added, called the skysail mast. At the head of the topmasts are cross trees in place of the top on the lower masts. Each of these masts carries its own yard, from which depends the square sail designated by the same name as the mast to which it belongs. Its lower corners are sheeted out to the extremities of the yard below, or, in case of the courses or lower sails, to the deck. The yards slide up and down their masts, the lower yards hanging in slings by their middle part, and most of them by lifts attached to the yard-arms, and passing thence through a block at the head of the mast. The foremast is about one tenth shorter than the mainmast, and is furnished with similar yards, rigging, and

sails; those of the two masts are distinguished by the terms main and fore. The mizzen mast of a ship carries no square sail hanging from the mizzen or, as it is commonly called, cross-jack yard, but a mizzen topsail, topgallant sail, and royal. In place of the lower square sail there is a fore-and-aft sail called a spanker, which extends aft from the mast over the taffrail, and is sheeted out to the end of a gaff above and to that of a boom below. This is of great service as a steering sail, acting as it pushes the stern off from the wind to bring the bow up as it is hauled in and kept flat. Similar sails are sometimes attached to the other masts and used for storm sails. The masts are supported by shrouds and stays. The former are strong ropes, each one $2\frac{1}{2}$ times as long as the mast, the head of which it encircles by its middle part. Several of these pairs are thus secured over the head of the mast, and the ends are brought down over the side, diverging as they descend. They terminate outside the ship in blocks called dead-eyes, which connect by a lanyard to others fastened on the outer edge of the channels or chain wales, which are heavy planking secured edgewise to the side of the vessel below the bulwarks. This edge is held down by iron braces bolted below to the futtocks. Though the main object of the shrouds is to hold the masts steady, they also serve as ladders, small ropes called ratlines being hitched across from one to another for steps. The topmast shrouds are set up by dead-eyes secured to the outer edge of the top, and this edge is braced down by iron rods or chains called futtock shrouds attached below to the upper part of the lower mast. The futtock shrouds and those of the topmast have ratlines also, but those for the masts still higher have none. The stays are ropes which support the masts longitudinally, starting generally from their heads, and secured to the foot of the next mast in front, those for the foremast to the bowsprit. The back stays pass from the heads of the topmast directly down to the chain wales, somewhat aft of the foot of the mast to which they belong. The stays that pass from the several masts forward sometimes support triangular fore-and-aft sails, called stay sails. The main and mizzen masts stand nearest together, the former somewhat aft of the centre, and both of them usually are set raking or inclining aft. The foremast stands well forward and upright. The bowsprit extends forward over the bow, rising at an angle of 30° to 33° , its heel resting in a step on the first deck below close to the foremast. A cap is fixed upon the head of it, presenting a round hole above the bowsprit, through which is passed the spar called the jib boom, which is the extension of the bowsprit. As the foremast is stayed forward to the bowsprit, and several fore-and-aft sails, called the foretopmast stay sail, jib, and flying jib, are supported on the stays between them, it is essential

that the bowsprit itself be well secured. This is done first by the bobstay, a very strong rope, sometimes double and triple, which connects the outer portion of the bowsprit with the stem; and by the bowsprit shrouds, which are ropes extending from the end of the bowsprit to the bows. The dolphin striker is a stiff brace or strut extending down from the outer end of the bowsprit; it is kept in place by the jib and flying-jib martingale stays and the back ropes. From the great angle which it forms with the head booms it amply counteracts the lifting effects of the jibs and the strain of the foretopgallant mast. The sails over the head booms are triangular. The rope by which their lower corners are made fast to the deck is called the sheet; this is also the name of the ropes by which the lower corners of the square sails are hauled out to the ends of the yards. Of the courses or lower square sails the corners on the lee side, which in sailing on a wind are hauled aft, are secured by sheets; but the corners on the windward side, which are hauled forward, are made fast to the deck by ropes called tacks. It is with reference to tending these, to shift them as the yard swings in going about, that the preparatory order is given of "Rise tacks and sheets," succeeded, as the evolution is completed, by "Let go and haul." The braces are the ropes by which the yards are swung round. The sail is made to lie still flatter by bowlines which are attached to the leach or edge of the square sails and lead forward. In sailing as close to the wind as possible, the weather bowline is hauled taut, whence the expression "to sail on a bowline," or "on a taut bowline," for lying up close to the wind. In running before the wind the yards are set at right angles to the line of the keel. The head sails are partially becalmed by the after ones, and the fore-and-aft sails over the head booms are of no service; the progress of the ship therefore is not so rapid as with the same wind on the quarter or abeam and filling all the sails. In order to spread a greater surface of canvas when the winds are light and fair, provision is made for lengthening the yardarms by means of booms called studdingsail booms, which are run out through an iron ring on the end of the yard, and to the outer extremity of which are hauled the tacks of the studdingsails. With a side wind these sails are advantageously carried on the weather side. The assemblage of ropes upon a ship, many of which have already been named, are known as the rigging. Those which are fixed, as the shrouds, stays, &c., are called the standing rigging; and the rest, as the halyards, sheets, and tacks, are the running rigging.—*Sails*. The larger sails are made of the heaviest No. 1 flax canvas, while the smaller are formed of lighter varieties running to No. 8 of the same material, known as duck of different degrees of strength. The strips of cloth are sewed together with twine, usually with a double seam,

and the patterns are skilfully cut for a smooth and even fit. The edges are bound around with a rope called a bolt rope to take the strain from the canvas, and in each corner an iron ring or thimble is inserted and held fast by a rope called a cringle, which goes round the outer concave surface of the ring, and is spliced each end into the bolt rope. Through these rings are passed the ropes, called earings, by which the sail is stretched or bent to its place. The same contrivance is repeated at one or two places on the edge of the sail, that it may be shortened in single or double reefing; and on the line horizontally with these earings short lengths of cord, called reef points, are secured through the sail and hang loosely on each side, which are used when the sail is reefed to tie around the part which is taken in. Sails may be classed as square sails and as fore-and-aft sails. The former hang by the earings and rope bands from yards, and are drawn out by the lower corners or clews to the ends of the yards below. They are made to swing round with the yards so as to present their surface to a side wind; but the fore-and-aft sails are better designed for sailing on the wind, and the square sails for running with a free wind. Shoulder-of-mutton sails and gaff topsails are triangular fore-and-aft sails, the foot of which may be attached to a boom, or in the latter case to the gaff, and the top, by which they are hoisted, terminates in a point against the mast. Lateen sails, much used in the Mediterranean, are suspended from a very long yard, which is hoisted by the middle from the deck. One end of the yard is brought down by a brace, and the other projects above the top of the mast, and rakes with it well aft. The sail serves very well as a fore-and-aft sail. The great superiority in the rig of American fore-and-aft vessels, by which they have been able to attain the highest speed of sailing craft, is in the great spread of their sails, their skilful cut, and perfect stretch, which causes them to keep full while their plane is more nearly in a line with the wind than could formerly be practised.—It belongs to the naval architect to determine the amount and disposition of sail which his ship is to carry. The former is proportioned to the immersed midship section, for every square foot of which a well designed ship may carry 35 or even 36 sq. ft. of plain sails, *i. e.*, courses, topsails, topgallant sails, jib, and spanker. Yachts often carry as much as 100 to 1. In regard to the manner of disposing the various sails, it is important that their common centre of effort should be at such a point that the ship when in trim will carry, on a wind, a small weather helm. It has been found that when the pressure of the wind on the sails forward of a perpendicular erected on the centre of load water line, is to the pressure on the sails abaft as .78 to 1, the ship will work well, all other conditions of a good ship being fulfilled.—*The*

Theory of Working Ship. The principle upon which a vessel is made to advance against the wind may be explained as follows: Sustained in a state of equilibrium in the water, she is readily susceptible to any force applied to change her position. This involves a movement of the water to admit her passing through it. On the line of the keel this easily takes place from the wedge-like shape of the hull; but a movement sidewise is resisted by the great body of water pressing against the hull for its full length. Whenever therefore the sails are filled by a breeze blowing against them from behind, even if at a considerable angle with the length of the ship, it is easy to perceive that her motion must be forward on the line of the keel. As the wind draws further forward the sails are braced further round, so that they may still receive it upon their after side. The wind of course strikes them to a greater disadvantage the nearer their plane approaches its direction; but so long as it impinges even obliquely upon their after surface, a portion of the force is exerted to press out the sails in a forward direction, while the remainder passes uselessly along the plain of the sails. The former portion tends to push the ship directly in a course at right angles with this plane; but the shape of the ship being opposed to this movement, this force also is resolved into two, one acting to propel the ship sidewise and the other forward. Thus this last result may prove effective even when the head of the ship is pointed obliquely toward the wind, as mentioned of fore-and-afters, at an angle of 40° or 45° , and in the case of ordinary sailing frigates at an angle of 60° . This may be shown by the annexed figure, where the sail A B, oblique to the line of the keel and to the wind V C, is impelled in the direction C D with a force expressed by the square of the sine of the angle of incidence A C V. If C D represent the

force of the wind on the sail, as expressed by the square of the sine of incidence A V, we have only to construct G H to see that such a direction is composed of the two effects C H and C G with respect to the body E F on which it acts. Now the sharper we brace the

yard A B, the more acute becomes the angle A C E, the effect of which is to augment O H and diminish O G. For as A C E becomes more acute the angle D C H is lessened, so that C D perpendicular to the centre of the yard will approach more to O H perpendicular to the keel E F. Hence a portion of the force is applied in the direction O G, the length of the ship. When braced sharp up, A C E = about 20° . On the other hand, the larger the angle A C E the more the effect O G will increase, in the same proportion as the increase of the sine of that angle when the impulse of the wind upon the sail is the same; for the sines of the angle are in proportion to their opposite sides in the triangle O D G, of which the angle C D G is equal to the angle A C E. Though, when sailing thus partially toward the wind, but a small portion of its propelling effect is available, something is recovered by its greater force caused by running against it; while in sailing in the opposite direction its effect is diminished by running away from it. If, after sailing for any time with the sails sharply braced, the head of the vessel can be brought round, so that the sails shall fill on the other side, the ship will proceed on the other tack on a line reaching further and further to the windward of that before passed over, and thus by a succession of zigzags progress is continually made against the course of the wind. This is called beating to windward, and the turning of the ship toward the wind and thence around is tacking. This is done as follows: The helmsman, having carefully kept the head of the ship as near the wind as practicable with the sails remaining full, at the order puts the helm gradually down, and soon after, at another order, "hard a-lee." As the head of the vessel is thus brought up toward the wind, the head sails are let fly by casting off their sheets, so that they shall present the least impediment in the way of this movement. The spanker on the contrary is hauled more toward the centre, that the wind continuing to strike it may push the stern round the other way. Soon the square sails on the foremast catch aback, or receive the wind on their forward side. This, while it checks the headway, also tends to throw the bow still further round. The after yards are then swung for the wind to strike them on the other side, and the same is next done to the head yards. As the sails fill, the ship soon gathers headway on the new tack. Fore-and-aft rigged vessels are much better adapted for working to windward than those with square sails. Their sails keep full at a smaller angle with the wind, and in going about or tacking they do not lose headway, but even run some distance directly in the eye of the wind, which other vessels are prevented from doing by their great square sails catching aback. As a storm comes up at sea, the first precaution is to shorten sail. The lighter sails are taken in and furled, and the topsails are first single-reefed, and next double-reefed;

mainsail is reefed; mizzen topsail close-reefed; next the fore and main topsail the same; mainsail is then furled, and the jib also. The foresail is then reefed and the mizzen topsail is furled. The main spencer may now be set, and the fore topsail furled unless the ship is too stiff. With close-reefed main topsail and reefed foresail, with the main spencer and stay sails, the ship is now under good sail for either running or lying to. With increasing wind and the ship lying to, the foresail may be taken in. When the main topsail is taken in, the last resort is setting tarpaulins in the weather mizzen rigging of the ship. The practice is somewhat varied with different ships according to their manner of working. In case the vessel does not lie to well, she may in a favorable lull of the storm be put before the wind, and run off under bare poles. An expedient sometimes resorted to with good effect is the drag. This may be made of spare spars with an anchor attached to give it a hold on the water. A long stout hawser secured to this and brought in over the weather bow will enable a ship to "cathead" the sea, and, with all sails snugly furled, ride out the heaviest gale. With such resources, ships at sea in good trim with plenty of room usually escape in the severest storms, sometimes indeed with the sails torn, the topmasts carried away, and occasionally with a mizzen mast cut away to ease the vessel, or otherwise dismantled. The great danger is in proximity to land, especially a lee shore.—Cables are made of rope and of iron, the latter being used the most in recent times. They are worked by means of a capstan or kind of windlass which may have a vertical or horizontal axis, and may be turned by hand or by steam. The method of making the different kinds of chain cables is given in the article CABLE. A table showing the comparative sizes of chain cables and anchors which are used together according to the United States navy regulations will be found in the article ANCHOR. The following table gives the navy regulation for the number, size, and length of both hemp and chain cables for ships of the line, frigates, and sloops of the first class:

SHIPP, Albert M., an American clergyman, born in Stokes co., N. C., Jan. 15, 1819. He graduated at the university of North Carolina in 1840, and was received into the South Carolina conference in 1841. He became president of Greensboro female college in 1848, professor of history and English literature in the university of North Carolina in 1849, and president of Wofford college, Spartanburg, S. C., in 1859, and was chosen to be professor of church history in the Vanderbilt university, Nashville, Tenn., in 1874. He has been a member of every general conference of the Methodist Episcopal church, South, since 1850.

SHIPPING. The law of shipping, the law of marine insurance, and the law of negotiable paper have a common origin in the custom of merchants. This custom and its authority ascend to a remote antiquity, and the books to which we must refer for it give us the rules of the commercial world during many ages. Many of the present rules and principles of the law of shipping have an earlier origin than anything in the common law, or indeed in any existing system of law. Even the Roman law, in the rubric *de lege Rhodia de jactu* (concerning jettison), quotes and confirms the law of Rhodes, whose commerce flourished at least 1,000 years before the Christian era. In the fragment to which we have alluded, the modern law of jettison, average, and contribution is as distinctly stated as in any recent text book; and in the title *de nautico fœnore*, which, however, like many other rubrics of the *Corpus Juris* relating to shipping, is not traceable to any earlier source than the law of Rome, we have the present rules regulating loans on bottomry and respondentia. Passing over several centuries, we find other still ancient but useful repositories of the customs of merchants and of the maritime law in the *Consolato del mare*, a collection or digest of the principal rules and usages established among commercial nations from the 12th to the 14th century, and in the laws of Oléron and the laws of Wisby, codes of maritime usages promulgated about the 12th or 13th century. Later, *Le guidon*, a book of the 16th century; the *Ordonnance de la marine* of Louis XIV., published in 1681, a work of the highest excellence covering the whole ground of maritime law; Valin's commentaries upon the ordinance; Cleirac's *Us et coutumes de la mer*; and the writings of Roccus and Casaregis, Italian juriconsults of the 17th and 18th centuries, reflect the commercial usages of their respective periods, and are the abundant, authoritative, and often sought sources of the modern law of shipping.—A ship is personal property, a chattel; and unless some positive law interposes, it may be transferred from seller to buyer by the same forms that attend the transfer of chattels of any other description; and in fact it can hardly admit of a doubt that an oral contract suffices to pass the property in a ship, and that no written evidence of the sale is essential to its validity. Still it is

the ancient usage of the maritime law to make a bill of sale or other written instrument the almost inseparable accompaniment and evidence of the sale, and it is convenient and proper that it should continue to be so. But apart from expediency and established usage, written evidence of the sale of a ship is made an essential condition of registration under the laws of the United States. Though the statute does not prevent the property from vesting in a purchaser under a merely oral contract, yet it renders a bill of sale a practically indispensable formality, because registration, of which it is the condition, gives to the ship all its substantial value as an instrument of commerce.—The laws which regulate commerce confer exclusive privileges in the carrying and coasting trade on United States ships. No merchandise may be brought from any foreign country to this except in American vessels, or in vessels belonging to that country of which the merchandise is the product, or from which it can only be or most usually is first shipped for transportation; and no merchandise shall be carried from port to port in the United States by any foreign vessel unless it formed a part of her original cargo. Ships intended for the fishing or coasting trade must, if not registered, be enrolled and licensed. In short, a ship that is neither registered nor enrolled and licensed cannot sail on any voyage with the privilege or protection of a national character or national papers. This national character and the benefit of it can be acquired only by compliance with the registry laws. The ships which may be registered under these laws are those built within the United States and owned wholly by citizens thereof, and those captured and condemned as prizes or adjudged forfeited by violation of law, if owned wholly by citizens of this country. No ship can be registered if an owner or part owner usually resides abroad, although a citizen, unless he be a consul of the United States or an agent for and a partner in a mercantile house established and doing business here; nor if the master be not a citizen of the United States; nor if the owner or a part owner be a naturalized citizen and reside in the country whence he came more than a year, or in any foreign country more than two years, unless he be a consul or public agent of the United States. If a registered American ship be sold or transferred in whole or in part to an alien, the certificate of registry must be delivered up, or the vessel is forfeited. As soon as a registered vessel arrives from a foreign port, her documents must be deposited with the collector of the port of arrival, and the owner, or, if he does not reside in the district, the master must make oath that the register contains the names of all persons who are at that time owners of the ship, and at the same time report any transfer of the ship or of any part that has been made within his knowledge since the registry, and also declare that no foreigner has any interest in the ship. If

a ship be transferred while at sea or abroad, the old register must be given up, and all the requirements of law as to registry must be complied with within three days after her arrival at the home port.—The rights of part owners of ships form an important branch of the law of shipping. Two or more persons may become part owners by building a ship together, or by joining in purchasing it, or each may purchase his share independently of the others; and their rights and obligations are the same in all these cases. A ship may form part of the stock or capital of a co-partnership, and then it will be governed in all respects by the law of partnership. But part owners are not necessarily partners. Any one of them may at any time sell his share, but he cannot sell the share of any other part owner without his authority. A majority of the owners may generally direct the employment of the ship at their discretion; but a court of admiralty will interfere to do justice between them, and prevent any one from inflicting injury on the others. In the absence of the rest, and without prohibition from them, one part owner may, in the exercise of good faith and a sound discretion, manage the ship as for himself and them; and the contracts into which he enters in relation to the employment or preservation of the ship bind all the part owners in favor of an innocent third party. In general, all the part owners are liable *in solido*, or each one for the whole amount, for all the repairs of a ship or for necessities actually supplied to her in good faith; but if it can be clearly shown that especial credit was given and intended to be given to one owner personally to the exclusion of the others, the others cannot be holden. One of the part owners generally acts as ship's husband. His ordinary duty and authority include equipping and repairing the ship, taking care of her while in port, furnishing her with all regular and proper papers, and making contracts for freight or passage. He cannot unless specially empowered make insurance, buy a cargo, borrow money, or surrender the owners' lien on the cargo for freight.—The owner of a ship may employ it in carrying his own goods or those of another. He may carry the goods of others while he himself retains the possession and direction of the ship, or he may lease it to others. In one case, he carries goods on freight; in the other, he lets his ship by charter party. When goods are carried on freight, the rights and obligations of ship owner and shipper are stated generally in the bill of lading, which is now in universal use among commercial nations with but little variety of form. It should contain the names of the consignor and consignee of the vessel, of the master, of the places of departure and destination; also the price to be paid as freight, with primage and other charges if any there be; and either in the body of the bill or in the margin the marks and numbers of the things shipped.

The bill should be signed by the master of the ship, who by the strict maritime law has no authority to sign a bill of lading until the goods are actually on board. One copy of the bill of lading is usually retained by the master, and three copies are given to the consignor; of these he retains one, and the others he sends to the consignee, one of them with the goods and the other by some other conveyance. The bill promises delivery to the consignee or his assigns. The consignee may designate his assigns by a particular indorsement, or he may indorse the bill in blank. As the bill is evidence against the ship owner as to the reception of the goods, and their quantity and quality, it is common to say: "Contents unknown." Yet between the ship owner and the shipper the bill is not conclusive, and the former may show that the goods were injured or destroyed on the passage by reason of some intrinsic defect, which was not apparent or easily to be ascertained when the goods were shipped. But if the bill has altered the situation of parties relying on its truth, so that either an innocent party must suffer or else the ship owner whose agent signed the bill either fraudulently or heedlessly, it is he and not the innocent party who must bear the loss.—The contract of affreightment is entire; therefore no freight is earned unless the whole is earned by carrying the goods quite to their destination. If the transportation is incomplete, having been interrupted by wreck or other cause, there is no absolute right of freight. Yet there is a conditional right; for as soon as the ship receives the goods, it not only comes under the obligation of carrying them to their destination, but at the same time, or perhaps more exactly, on breaking ground and beginning the voyage, acquires the right of so carrying them. Therefore, if any interruption intervene, the ship owner has the right of transshipping the goods and carrying them on to their original destination. The goods are to be delivered by the bill of lading in good condition excepting "the dangers of the seas," and such other risks or perils as may be expressed. Damage caused to goods by an excepted risk is therefore the loss of the shipper or consignor, and not the loss of the owner. But if goods are lost in substance, even if not in form, as if sugar is washed out of boxes or hogsheds, or wine leaks out of casks by reason of injury sustained from a peril of the sea, though the master may deliver the hogsheds or casks, this is not a delivery of the sugar or of the wine, and no freight is due. But freight must be paid if the goods are injured or actually perish and disappear from any internal defect or decay or change; that is, from causes inherent in the goods themselves. If goods are delivered, although damaged and deteriorated from faults for which the ship owner is responsible, as bad stowage, deviation, negligent navigation, or the like, freight is due, the amount of the damage being first deducted. The rules in respect to passage money are quite

analogous to those which regulate the payment of freight; but as the money is not earned except by carrying the passenger, or *pro rata* by carrying him a part of the way with his consent, it may be recovered back when it has been paid, as it usually is, in advance, and not earned. Not only is the owner of the ship bound to the owner of the cargo, as soon as he receives it, to lade it properly, to take care of it while on board, to carry it safely, so far as the seaworthiness of the ship is concerned, to its destined port, and then deliver it all in a proper way, but the ship itself is bound to the discharge of these duties.—An owner, we have said, may let his ship to others. The instrument which contains the evidence of such a contract is called a charter party, an ancient name, the origin of which is not quite certain. The form of the instrument varies with the bargain between the parties. Generally only the burden of the ship is let, the owner holding possession of her, finding and paying master and crew, supplies and repairs, and navigating her as is agreed upon. Sometimes, however, the owner lets his ship as he might let a house, and the hirer takes possession, mans, navigates, supplies, and even repairs her. The charter party should designate particularly the ship and master and the parties; should describe the ship generally and particularly as to her tonnage and capacity; should designate especially what parts of the ship are let, and what parts if any are reserved to the owner or to the master to carry goods, or for the purpose of navigation; should describe the voyage or the period of time for which the ship is hired with proper particularity; and should set forth the lay days, the demurrage, the obligations upon either party in respect to the navigation or furnishing of the ship, and all the other particulars of the bargain. Lay days are those which are allowed the charterer for loading or unloading the vessel. If more time than these agreed lay days is occupied, it must be paid for, and the amount thus paid is called demurrage. By the charter party the hirer (or charterer) usually agrees to pay so much demurrage a day. If time be occupied in repairs of the ship which are made necessary without the fault of the owner or master or of the ship itself, that is, if they do not arise from her original unseaworthiness, the charterer pays during this time. But generally speaking, there is no claim for demurrage on the charterer for any delay which is induced by the action of the elements, as ice, tide, or tempest, or from any act of government, or from any real disability of the consignee which could not be imputed to his own act or to his own wrongful neglect. The contract of charter party may be dissolved by the parties by mutual consent, or without their consent by any circumstance which renders the contract illegal; as for example, a declaration of war, an embargo, or a blockade.—In the navigation of the ship, the whole care and supreme command are intrust-

ed to the master. He must see to everything that respects her condition, including her repairs, supplies, loading, and unloading. He is principally the agent of the owner, but is to a certain extent the agent of the shipper and of the insurer, and of all who are interested in the property under his charge. Much of his authority as agent of the owner springs from necessity. In a case of extreme necessity, he may even sell the ship; he may pledge her for a debt by a bottomry bond; he may charter her for a voyage or a term of time; and may raise money for repairs or incur a debt therefor, and make his owners liable. Generally the master has nothing to do with the cargo between the lading and the delivery; but if the necessity arises, he may sell the cargo or a part of it at an intermediate port if he cannot carry it or transmit it, and it must perish before he can receive specific orders. So he may sell it or a part of it, or pledge it by means of a respondentia bond, in order to raise money for the common benefit. A bond of respondentia is much the same thing as to the cargo that bottomry is as to the ship. It secures money borrowed at maritime interest and on maritime risk by pledge of the goods, and the debt is discharged when the goods perish. The owner is liable for the master's wrong doings; that is, for every injury done by the master while acting in that capacity.—Under our pilotage laws, every ship entering or leaving a harbor must, within certain limits, accept the services of a pilot if they are offered, or pay the prescribed fees even if those services are declined; and if a ship neglect to take a pilot when it should and can do so, the owners will be answerable in damages to shippers or others for any loss which may be caused by such neglect or refusal. As soon as the pilot stands on deck he has control of the ship, and is answerable for any damage resulting from his own negligence or default. Yet it remains the master's duty and power, in case of obvious and certain disability, or dangerous ignorance or error, to disobey the pilot and dispossess him of his authority.—See also AVERAGE, BOTTOMRY, SALVAGE, SEAMAN, and STOPPAGE IN TRANSITU.

SHIP WORM, or *Pile Worm*, the popular name of the bivalve shells of the family *pholadidae* and genus *teredo* (Linn.), so called from their perforating ship and other timber. The shell is thick, short, globular, equal-valved, widely open in front and behind, lodged at the larger or inner extremity of a cylindrical tube, straight or sinuous, partly or entirely lined with white calcareous matter, and often open at both ends. The valves are reduced to mere appendages of the foot; in the centre of their circular opening this organ is protruded, the whole forming a very effectual boring apparatus, which is indicated by their peculiar shape, strength, arrangement of the valvular ridges, and great size of the adductor muscle. The animal is elongated and worm-like, the length

being due chiefly to the prolongation backward of each respiratory tube, the siphons of which are provided with two calcareous triangular flattened plates, the *palettes*, which are always turned to the external aperture. The best known species is the *teredo navalis* (Linn.), whose calcareous tubes are from 1 to $2\frac{1}{2}$ ft. long. They attack wood immersed in sea water, boring in the direction of the grain, and turning out only for a hard knot, or a companion whose presence they detect by the sense of hearing; the dust of the rasped wood is introduced by the foot into the cavity of the mantle and swallowed, and is usually found filling the long intestine. They are ovoviviparous, and the young after leaving the body of the mother have a smooth bivalve shell, swim by means of long vibratile cilia, and creep by the tongue-shaped foot; they soon attach themselves to wood and begin to bore, secreting the calcareous tube as they go along; they grow in the wood and enter it when young, as is evident from the external aperture being too small to admit the body of the enclosed adult. From the tropical seas they have been introduced into the temperate waters of Europe and America, and in many places have been exceedingly destructive. The best protection has been found to be metal sheathing and broad-headed nails; and in some cases kyanizing or otherwise poisoning the timber has prevented their attacks. Other species have been found whose tubes extend from 3 to 6 ft., with walls $\frac{1}{8}$ to $\frac{1}{2}$ in. thick, and some-

perforates floating wood. The perforations are generally for a few feet below low-water mark, and in preference in the direction of the grain between the annual rings; and their

Wood Perforated by Ship Worm.

numbers are so great that by the time one has perforated an inch the timber is riddled. They are common on both sides of the Atlantic, and are everywhere destructive. They may be guarded against in the same manner as the *teredo*. These creatures have their uses in disintegrating sunken vessels and substances which would obstruct navigable channels.

SHIRAZ, a city of Persia, capital of Faristan, in a beautiful and well cultivated plain, about 4,750 ft. above the sea, 217 m. S. by E. of Ispahan, and 115 m. E. N. E. of Bushire; pop. about 40,000. There are few other Persian cities so substantial in construction, or so attractive in appearance and surroundings. The

walls are nearly 4 m. in circumference, and the buildings within are constructed principally of stone and a mixture of sun-dried and kiln-dried bricks. Among the finest are the citadel, the mosques sur-

Ship Worm (*Teredo navalis*).

times diverging into two; one burrows in the husks of cocoanuts and other woody tropical fruits floating on the ocean, making very crooked channels. For details see the abstract of a paper read before the national institute at Washington, D. C., by James Jarvis, giving the results of his experiments since 1849 on various kinds of timber, in the "Annual of Scientific Discovery" for 1857, p. 359.—Another pile or timber worm is a minute sessile-eyed crustacean, of the order *isopoda*, and genus *limnoria* (Leach). The best known species is the *L. terebrans* (Leach), $\frac{1}{8}$ to $\frac{1}{2}$ in. long, rounded at each end, with sides parallel; there are 14 segments, the last two much the largest, the seven next to the head each bearing a pair of short legs; there are two pairs of jaws and a pair of strong mandibles, which are the boring organs; the general color is olive-gray. It can swim as well as creep. All wooden structures immersed in salt water are attacked by it, especially sea bulwarks, and the piles and piers of bridges, docks, and canals; it rarely

mounted with domes of green and blue, the bazaars, and the largest of the ten colleges. Considerable portions of Shiraz are ruined and dilapidated. The adjoining plain is exceedingly fertile, abounding in fruits and flowers, and the rose gardens of the suburbs are celebrated throughout the world. The position of Shiraz on the trade route between Ispahan and the Persian gulf makes it a place of considerable commercial importance; and it is a station of the Indo-European telegraph. In addition to rose water, wine of a very fair quality resembling Madeira, and tobacco of remarkable fragrance, are the chief industrial products of vegetable origin. Glass bottles and sword cutlery are manufactured. It has a mint, and its lapidaries are renowned for their skill.—Shiraz was founded in the 7th century, captured by Tamerlane in 1387, and made the capital of Persia by Kerim Khan in 1760, who greatly enriched and beautified the city. It was visited by severe earthquakes in 1812, 1824, and 1853, the last one being very destruc-

tive. It is famous among Persians as the birth-place and residence of the poets Saadi and Hafiz, both of whose tombs are in the neighborhood. There are numerous antiquities in the vicinity, including the ruins of Persepolis.

SHIRE. See COUNTY.

SHIRÉ, a river of S. E. Africa, which flows out of the S. extremity of Lake Nyassa, and after a southerly course of about 300 m. falls into the Zambesi, 90 m. above its mouth. A series of rapids, about 40 m. long, terminating 100 m. from the Zambesi, separates the upper from the lower valley of the Shiré, by a descent of 1,200 ft. Except in these cataracts the river is navigable for boats, being nearly 150 yards wide and from 12 to 15 ft. deep at its point of exit from the lake, while it enters the Zambesi with a width of 200 yards. Its upper course is broad and deep, and one day's march S. of Nyassa it expands into a lake 10 m. long and 5 m. wide, known as Pamalombe. Below the rapids the river flows over great shallows, and through marshes choked with aquatic vegetation. The Shiré was first explored in 1859 by Livingstone.

SHIRLAW, Walter. See supplement.

SHIRLEY, James, an English dramatist, born in London about 1594, died Oct. 29, 1666. He graduated at Catharine hall, Cambridge, took orders, and was appointed to a living in Hertfordshire, which he soon resigned, having become a Roman Catholic. After teaching a few years in the grammar school of St. Albans, he settled about 1625 in London as a writer for the stage. He had produced 33 plays when parliament in 1642 prohibited theatrical performances. He fought in the civil wars under the earl of Newcastle, and afterward resumed teaching. The great fire of London drove him and his wife into the suburbs, where from exposure they died on the same day and were buried in the same grave. He published five grammatical treatises, assisted in the composition of several plays published by his patron Newcastle, and wrote the notes for Ogilby's translations of Virgil and Homer. His "Traitor," partly recast by Sheil, was produced at Covent Garden theatre in 1819, under the title of "Evadne, or the Statue." The only collection of his works is that of Gifford and Dyce (6 vols. 8vo, London, 1833).

SHIRWA, a lake in S. E. Africa, 30 m. S. by E. of Lake Nyassa, and separated from the valley of the Shiré river to the west by a mountain ridge having an estimated elevation of 7,000 ft. It is 60 m. long from N. to S., 20 m. wide, and about 2,000 ft. above the sea level, with brackish waters and no known outlet. It was discovered by Livingstone, April 18, 1859.

SHOA, one of the great political divisions of Abyssinia, in the S. E. corner of that country, sometimes under the same sovereignty and at others an independent state, situated between lat. 8° 30' and 11° N., and lon. 38° and 40° 30' E. Its boundaries are ill defined, but it is bordered N. W. by Amhara, N. E. by

Adal, E. by the Galla desert country, S. by the river Hawash, and terminates on the W. in the valley of the Abai; pop. estimated at 2,500,000, of whom 1,000,000 are Coptic Christians and the remainder Mohammedans and pagans. Shoa consists of a series of plateaus, varying from 3,000 to 10,000 ft. in height above the level of the sea. A mountain range traverses the country from S. W. to N. E., forming an eastern watershed down which flow the affluents of the Hawash, while the western slope gives rise to the Jamma, one of the principal tributaries of the Abai. The valley of this river occupies the central and western part of Shoa, at an elevation of about 3,000 ft. A broad plain lies between the mountains and the Hawash river on the south, and from the highlands the descent is rapid through the eastern part of the country, called Efat, to the desert. Shoa is watered by numerous streams; the soil is fertile, and large crops of grain are raised. The higher lands are used chiefly for pasturage. The valleys are very beautiful and well wooded, but in summer they are hot and unhealthy, and particularly subject to fever. They produce coffee, cotton, drugs, and different sorts of dye woods. Ancient volcanic rocks predominate in the geology of Shoa. Iron and sulphur are the chief mineral products, and coal is said to exist. It has but little external trade, and its foreign commerce is carried on principally through ports on the gulf of Aden. There is a caravan route from Ankobar to Tajurrah, on the gulf of that name, but the difficulty of transporting goods across the desert is very great. Gold dust, spices, gums, ostrich feathers, and ivory are the chief exports, but some of these articles merely pass through the country from the surrounding territories. Cotton cloth is manufactured, and the natives work in iron. Ankobar, the capital, is situated on the eastern highlands, near the mountain range already mentioned, in lat. 9° 35' N., lon. 39° 54' E., 8,198 ft. above the sea, and enjoys a climate of perpetual spring; pop. about 10,000.—Shoa has frequently been a province of the Abyssinian monarchy, but is now an independent kingdom. The British government established friendly relations with the country in 1841, through a diplomatic mission under Major Harris. The government is an absolute despotism, and the name of the present king (1875) is Menelek.

SHODDY, a rag wool obtained from old blankets, stockings, carpets, flannels, &c., and now largely employed together with the similar article called mungo, obtained from old woollen garments and tailors' clippings, in mixing with new wool for manufacturing blankets, druggets, carpets, table covers, pilot cloths, petershams, &c. In some of these rag wool constitutes nine tenths of the whole material, and in others not more than one tenth. Its use in some degree is the cause of the apparent cheapening of many kinds of woollen goods within a few

years. In some parts of England the business of working up woollen rags is very extensive. About one third of the whole amount is produced at Batley, Yorkshire, and the remainder in neighboring towns. The rags pass through a number of hands in the course of preparation for the powerful machines employed in tearing them to fibres. In the United States shoddy has become a manufacture of considerable importance, and the article is also imported from England. The manufacture in Germany is also extensive. Its presence is detected in wearing garments by the collection of rolls of short wool between the cloth and the lining. Unless the admixture is excessive, the wear of the cloth is not materially affected.

SHOE, a covering for the foot, commonly made of leather. If furnished with a top for enclosing the lower part of the leg, it is called

FIG. 1.—Sandals. 1. Foot of Statue of Elpis, in the Vatican. 2. Female Foot with simple Sandal. 3. Foot of Apollo Belvedere.

a boot. The oldest form is that of the sandal, a flat sole to be worn under the foot, and secured to it by thongs in various ways, as shown in the accompanying illustration. The ancient Egyptians made sandals of leather, and others for the priests of palm leaves and papyrus. Specimens from their tombs are preserved in the British museum, formed of strips of palm leaf nicely fitted together and furnished with bands of the stem of the papyrus. The Hebrews used similar protections for the feet, sometimes formed of linen and of wood, while those for soldiers were of brass or iron. Among the ancient Greeks and Romans the use of shoes was not general. Spartan youths were trained to go barefoot, and the heroes of

FIG. 2.—Shoes. 1. From an Antique Statue. 2. Foot of the Statue of Hermes in the Vatican. 3. From a Statue of Demosthenes in the Vatican.

Homer are usually described as without shoes when armed for battle. Greek women, however, wore shoes, and their use finally became universal. There was great diversity in their fashion, and the several sorts were named from the person who introduced them or from the place whence they came; as the "shoes of Alcibiades," "Persian," "Cretan," "Athenian shoes," &c. The Spartans wore red shoes, and the same were put on by the chief magistrates of Rome on ceremonial occasions. The *calce-*

us was like modern shoes in form, covering the whole foot, and tied with lachets or strings. Those of senators and patricians were high like buskins, ornamented with an ivory crescent, and called *calcei lunati*. Some were made with tops, and of all lengths, even to covering the whole leg; these were called *calceamenta* and *cothurni*. The tops were often of the skins of wild animals, lacing up in front, and ornamented at the upper extremity with the paws and heads arranged in a flap that turned over. The skin was dyed purple or some other bright color, and the shoes were variously ornamented with imitations of jewels, and sometimes with cameos. It was common to make them open at the toe, so that this part of the foot was left exposed.—Wooden shoes were in common use throughout Europe in the 9th and 10th centuries, and were worn even by the first princes; but sometimes highly ornamented leather sandals or shoes were worn. Great attention was directed in the middle ages to this portion of the dress, as well as to

FIG. 3.—Shoe and Boot. 1. Shoe, from an Antique Statue. 2. Hunting Boot, from a Statue of Diana.

FIG. 4.—Shoe of Charlemagne, Abbey of St. Denis.

the covering for the head (see **HAT**), and equal extravagances were adopted in both articles. The shoes were worn of different colors, and the stockings also were unlike each other, and of different colors from either of the shoes. In the reign of William Rufus a famous beau, Robert, surnamed the Horned, introduced shoes

FIG. 5.—1. From a Portrait of the Emperor Frederick III. 2. Italian Shoe of the 14th Century.

with long-pointed toes twisted like a ram's horn. Though strongly inveighed against, the style became fashionable, and in the reign of

Richard II. the points had increased to such an extent that they reached the knee, to which they were secured by chains of silver or gold. The upper parts were cut to imitate the windows of a church, and the whole was made extravagantly conspicuous. For three centuries the clergy, popes, and public officers sought in vain by declamations, bulls, and orders to break up the fashion. By act of parliament in 1463 shoemakers were prohibited from making for the "unprivileged classes" any shoes with points more than 2 in. long; and afterward excommunication was denounced against any person wearing such. The extravagant taste was then directed to the width of the toe, till at last Queen Mary was impelled to restrict this by proclamation to 6 in. In the 16th century shoes were made of elegant buff-colored Spanish leather, with tops of enormous dimensions spreading over so widely as to obstruct the movement of the feet. The Puritans wore such boot tops, and after the restoration of Charles II. the French custom was introduced of ornamenting the upper edge with lace. The present simple form of shoe was adopted in the early part of the 17th century, and in the latter portion of the same the shoe buckle began to be used. During the succeeding century this continued to be very conspicuous, and so many were dependent upon its manufacture in England that, when it began to be unfashionable in the commencement of the present century, the prince of Wales sought to keep up the custom for the sake of the buckle makers. Shoes worn by ladies in the last century were sometimes very elaborate and costly, made of bright-colored silk, ornamented with gold or silver stars and binding of different colored silks from the shoe itself. Of all the diversities of shoes worn by various nations, none are so strange and unnatural as the slippers of the Chinese ladies of rank. From childhood the growth of their feet is checked by bandages at the cost of extreme suffering. They are thus enabled to wear shoes only 3 or 4 in. long, which are most unquestionable evidences of their high rank. The shoes are of silk beautifully embroidered with designs in gold and silver thread and colored silks. In European countries wooden shoes (Fr. *sabots*) are in very general use among the peasantry; they are cheap and durable, and, though clumsy, are said to be comfortable. In this country an attempt to manufacture wooden shoes was made on a large scale in 1863, but the market was found to be limited, and very few are now made.—In the manufacture of shoes the highest perfection has been attained in the United States, due chiefly to the ingenuity and enterprise of the mechanics of Massachusetts. In Lynn the making of women's shoes had been a prominent industry almost from its first settlement. The business was conducted by the families of the manufacturers, and with no especial skill until the settlement there in 1750 of a Welsh shoemaker named John Adam

Dagyr. By his superior workmanship he acquired great fame in the trade, and materially improved the style of the work in that region. During the revolutionary war Massachusetts supplied great quantities of shoes for the army; but soon after its close the business was seriously checked by large importations. In Lynn however it revived, so that in 1788 its exports of women's shoes were 100,000 pairs. In 1795 200 master workmen were employed there, besides 600 journeymen and apprentices; and about 300,000 pairs of shoes were sent away, chiefly to southern markets. From the cities some were exported to Europe, and also direct from Lynn. The business continued steadily to increase, until it amounted in 1874 to a production estimated at about 11,000,000 pairs, of the total value of \$14,000,000, and giving employment in the busy seasons to more than 10,000 operatives. The work is not continuous, there being about three months of the year when most of the operatives are idle or engaged in other pursuits. The shoes produced in Lynn are nearly all for women, misses, and children, the uppers of which are largely of lasting or serge, though a considerable quantity are of morocco, kid, and grain leather. Men's shoes are also made to some extent of calf and serge. Lynn work is distinctively known in the trade as embracing all the lighter grades to be found in the ordinary retail shoe stores, and it is made to sell at the lowest prices for which a light and cheap shoe can be produced. It is all "sewed" work, and for the greater part the bottoms are put on by the McKay machine, which sews through the outsole, insole, and upper. All those not so bottomed are known as "turns," or shoes in the making of which the sole is attached with the shoe wrong side out, after which it is turned and lasted in finishing. A large portion of these shoes are made by hand, the work being done out of the shops in families in Lynn and vicinity; but there are two well known machines, the Goodyear and the McKay, for sewing bottoms on "turn" shoes. Next in importance to Lynn, among the shoe manufacturing towns of Massachusetts, is Haverhill, where a generally better quality of shoes is made, including both sewed and pegged work of every kind. Next come Marblehead, Worcester, Marlboro, Milford, the Abingtons, Spencer, the Bridgewater, Brockton, the Weymouths, North and South Braintree, Brookfield, Beverly, Medway, Randolph, Stoughton, Danvers, Quincy, and several other places. In Maine and New Hampshire there is also an important shoe manufacturing industry, which is principally carried on at Portland, Auburn, and Lewiston, Me., and at Dover and Farmington, N. H. The business of buying the materials which enter into these goods and selling the productions is nearly all done in Boston, whose merchants are the principal owners of all the largest factories. There are no returns by which the exact production

can be definitely ascertained; but about three fourths of the goods made in the shoe towns of eastern Massachusetts, as well as some from Maine and New Hampshire, are shipped from Boston, and these shipments have been as follows for 10 years: 1865, 720,000 cases; 1866, 820,000; 1867, 920,000; 1868, 1,010,000; 1869, 1,340,000; 1870, 1,260,000; 1871, 1,310,000; 1872, 1,450,000; 1873, 1,340,000; 1874, 1,375,000. A case of women's or children's shoes regularly contains 60 pairs, and of men's boots 12 pairs are packed to a case; it is therefore probably below rather than above the actual amount to estimate the total shipments from Boston to places outside of New England for the year 1874 at 55,000,000 pairs. There is a very wide difference in the prices, as the goods comprise everything from a carpet slipper to a farmer's brogan, from a gentleman's fine calfskin boot to a miner's iron-clad shoe. But on an average they sell for about \$45 a case, making a total for the reported shipments for 1874 from Boston of \$61,875,000. By a careful estimate, the value of the boots and shoes made in Massachusetts and the shoe towns of Maine and New Hampshire is placed at \$100,000,000 per annum. While Boston is the leading wholesale shoe market of the United States, New York is entitled to the next place in importance as the distributing point for a great portion of the country, and for the manufacture of what are known as fine goods. Its work is the very best made in the country, and surpasses any factory-made boots and shoes in the world. In these goods only the best grades of French and German calf and kid skins, and the best morocco of domestic manufacture, with oak-tanned sole leather, are used. The work for ladies, misses, and children is nearly all machine-sewed, but of the best men's work a large proportion is made by hand. The production in the city of New York in 1874 amounted to about 3,000,000 pairs, of an estimated value of \$10,000,000. Next to New York may be classed Philadelphia, after which come Baltimore, Chicago, Cincinnati, St. Louis, and many smaller places throughout the Union. The imports of boots and shoes into the United States are insignificant, those entered at New York for 1874 having an aggregate value of only \$41,270. The exports for the same year from New York were \$202,593, almost entirely to the West Indies and Central America. The total exports from the United States for 1874 were 302,218 pairs, valued at \$448,138; for 1873, 215,308 pairs, valued at \$351,318.—Excepting possibly England, no other country in the world is so generally supplied with factory-made shoes as the United States. Throughout Europe the cobbler and the journeyman shoemaker still do a large part of the business. In England the factory system, with very much the same machinery and a similar division of labor as in the United States, supplies by far the greater part of the shoes called for by the

British home trade, and its vast demand for export to all quarters of the globe. The manufacture of boots and shoes in England is principally carried on at Leeds and in its vicinity, in the northern part of the kingdom, and at Northampton, as well as in the city of London.—It would require a volume to give a full list of all the boot and shoe machinery made, with even brief mention of the uses of the different kinds. The pegging machine, one of the most important, is principally due to Alpheus C. Gallahue, to whom were granted six different patents, the first in 1851. Elmer Townsend and B. F. Sturtevant, of Boston, largely aided in perfecting the invention of Gallahue; but it was not until about 1858-'60 that it came to be generally introduced. There were 1,700 pegging machines in operation in the United States in 1873. A machine is capable of pegging two pairs of women's shoes in a minute, and will put in one, two, or three rows of pegs at once, as may be required. The pegs are cut, by the working of the machine, from ribbon-like strips of white birch, which are supplied in rolls of from 75 to 150 ft. in length. About 1,000 cords of wood are required yearly for the manufacture of pegs in this country, but large quantities are regularly exported. Of equal importance with the pegging machine is the McKay sole-sewing machine, known in England and on the continent of Europe as the "Blake" machine. It was invented about 1858 by Lyman R. Blake, but was perfected and introduced into use by Gordon McKay. By this machine the soles can be sewed on nearly 100 pairs of women's shoes in an hour, and 800 pairs in a day of ten hours is fair work for an experienced operator. A royalty payable in stamps is required on all goods made on this machine, as follows: on slippers and misses' and youths' shoes, 1 ct. a pair; women's and boys' shoes, 2 cts.; men's boots, 3 cts. The income of the McKay machine association from the sale of stamps has been as follows: 1863, \$38,746 51; 1864, \$99,157 63; 1865, \$150,776 15; 1866, \$181,404 97; 1867, \$210,225 36; 1868, \$286,011 93; 1869, \$356,026 06; 1870, \$400,011 08; 1871, \$486,083 09; 1872, \$564,501 22; 1873, \$529,973 81. This machine is in such general use that a statement of the number of machines employed in different localities will give a very fair general idea of the distribution of the manufacture. In 1874 there were 1,200 of them in use in the United States, over 400 in England, and about 100 on the continent of Europe. Of those in the United States, 180 were employed in Lynn, 50 in Haverhill, 300 in the state of Massachusetts outside of these two places, 180 in the other New England states, 100 in New York, 90 in Philadelphia, 150 in the western states, and 130 in the southern. There are two other kinds of sole-sewing machines, viz.: the Goodyear welt machine, which makes a shoe in almost perfect imitation of hand work, and the Goodyear and McKay machines for making "turns."

For stitching the uppers of shoes several machines are in use, chief among which, both in this country and in Europe, are the Elias Howe and the Wheeler and Wilson. Next in importance to the pegging and sewing machines should be ranked cable-screw wire and wire-tacking machines, which have come into extensive use within a few years. After these come machines for setting and burnishing the edges of the soles, for making and trimming heels, for forming and beating out the sole, as well as for cutting it out, for rolling and splitting the leather, for sandpapering, eyelet making, &c. These machines, together with scores of less importance, are all of American invention, and most of them have been adopted in the shoe factories in other parts of the world. The attempt to introduce machinery on a large scale was first made in England, where in 1809 a patent was granted to David Mead Randolph for a method of riveting soles and heels to the uppers instead of sewing them together. He used a last sheathed on the bottom with an iron or steel plate. On this plate he laid the inner sole, and brought the edges of the upper leather around, and temporarily fastened them. The outer sole was then applied and secured by small nails driven through the three thicknesses and clinched against the plate. The first large manufactory with machines for expediting the operation was established in Battersea, by Brunel, the famous engineer, and it was carried on by the invalid soldiers of Chelsea hospital for supplying shoes to the British army. The shoes were made with a welt riveted to the edge of the outer sole by small nails, and a row of longer nails outside of these secured the whole to the uppers and inner sole. The bottoms were studied with short nails of copper or iron to improve the wear. Several ingenious machines, worked mostly by treadles, or otherwise by a winch turned by hand, were devised by Brunel for the various processes, as cutting out the leather, hardening it by rolling, punching the holes for the nails, forming the nails from slips of metal and inserting them in the holes, both by one machine, and for the others connected with the securing of the parts together. The machines do not appear to have continued in use after 1815, when on the establishment of peace the demand for army shoes fell off, and manual labor being more abundant the machines were of less importance. It was not until English manufacturers had generally adopted the American factory system and American machinery, that any large portion of the total production was supplied by the use of machinery. The wooden peg, now used for fastening boots and shoes, which has largely contributed to cheapening these articles, was invented about

1818 by Joseph Walker of Hopkinton, Mass.—In a modern shoe factory the division of labor on the various parts of a shoe is carried to its greatest extent. The uppers and linings are cut and stitched generally in one department, where the buttonholes are worked by hand or by a machine especially adapted to that purpose, and the buttons put on or eyelets punched, if for a laced shoe. The uppers being ready, the first process in bottoming is to wet the soles, which, after being partially dried, are passed under a heavy roller, which takes the place of the shoemaker's lapstone. They are then, if for machine sewing, after being properly cut out for the requisite sizes, run through a channelling machine, which takes out a thread of leather from the outside edge in the bottom of the sole, leaving a thin narrow flap all round, so that when the stitch is laid in the place of the leather thus removed the bottom may be hammered down so smoothly as hardly to indicate where its surface was raised to allow of the stitching. The upper is then drawn over the last and tacked on the insole, and the outsole is tacked on. The last is now withdrawn, and the shoe passed to the sewing machine, where the stitch is made through the outsole and insole, and the edge of the upper coming between them, the flap raised for the channel being laid and cemented over the seam. The heel is now put on in the rough, and the edges of both heel and sole are trimmed and burnished. In making a "turn" shoe, the sole is shaped before tacking to the last, on which it is placed with the grain side of the leather, or that which is to form the bottom of the shoe, next the last; the upper, with the stiffening in, is then pulled over, wrong side out, then lasted and sewed, the last being taken out after sewing, and the surplus upper cut away. The shoe is then turned right side out, first at the seat, then the ball and toe, the last again put in, and the sole and stiffening hammered into proper form. A "team" of shoemakers consists of from four to nine men, comprising lasters, heelers, trimmers, burnishers, and finishers, who complete the shoe, after the uppers are made and the soles cut out. But the number of men in a team and the way in which the work is divided up are altogether dependent upon the kind of work. What is called custom work, or making boots and shoes to measure for individuals, has of late years become comparatively obsolete. The styles of boots and shoes have not varied to any great extent for many years, the extremes of fashion having been from a long, narrow sole to a short and very broad one, with at times what is known as a "box" toe, and from a small, high heel, of from $1\frac{1}{2}$ to 2 in., to one of about an inch, more broad and comfortable.

SUPPLEMENT TO VOLUME XIV.

PROTAIS

PROTAIS, Paul Alexandre, a French painter, born in Paris in 1826. He accompanied the French forces to the Crimea and Italy, having devoted himself to military subjects from the beginning of his career. Of his numerous pictures the most important are "The Battle of Inkerman," "Taking of a Battery of the Mamelukes," "The Last Thought," "Brigade of General Cher on the Route to Magenta," "Passage of the Sesia," "A Sentinel," "The End of the Halt," "An Interment in the Crimea," "The Conqueror's Return to the Camp," "A Wounded Soldier," "The Night of Solferino," "The Army of Metz," "Prisoners, near Metz," "Swiss Guards," "The Morning before the Attack," and "The Evening after the Combat." The last two are considered his masterpieces.

PUVIS DE CHEVANNES, Pierre, a French painter, born in Lyons about 1840, died in 1871. He studied with Henri Scheffer and Couture, and devoted himself largely to mural painting. His works include "Ave Picardia Nutrix" (a monumental work containing eight figures, in the museum at Amiens), "Massilia, a Greek Colony," "Marseilles—the Gate of the Orient," "The Beheading of St. John the Baptist," "Mary Magdalene in the Desert," "Peace" and "War," and "The Year 732—Charles Martel saved Christianity by his Victory over the Saracens near Poitiers."

PUZZLES. From Samson's riddle, 1141 B. C., to the fifteen or gem puzzle of A. D. 1880, all nations and ages have put forth inventions to test the ingenuity and patience of the human mind. For a week the thirty young men puzzled over Samson's riddle, "Out of the eater came forth meat, and out of the strong came forth sweetness" (Judges xiv. 12), with the incentive of thirty changes of garment at stake on their success. The hand of King Oreon's sister and the crown of Thebes were the prize that Œdipus won in solving the famous riddle given by the Sphinx. Having perplexed the people of Boeotia with "What animal goes on

PUZZLES

four feet in the morning, two at noon, and three at night?" devouring all those who were unable to guess the answer, the Sphinx fulfilled her promise of self-destruction when Œdipus answered, "Man," and explained that her morning, noon, and night symbolized infancy, manhood, and old age. The first style of human speech abounded in enigmas; for what else are the emblems, symbols, and allegories with which the literature of the primitive peoples is filled? When Cyrus invaded Scythia, and received through a messenger from the people arrows, a rat, and a frog, to signify to him that unless he hid himself in the ground like a rat, or in the water like a frog, he could not escape the arrows of the Scythians, they proposed to him an enigma. In antiquity great truths and discoveries were not given to the people in simple language, but, couched in riddles, were communicated to a few disciples, who unravelled them at their leisure. Timæus of Locri, in explanation of God's infinity, proposed to his followers, "What is a circle whose centre is everywhere and circumference nowhere?" The ancient kings of Babylon and Egypt sent to each other enigmas to solve, and he who returned a wrong answer, or none, paid tribute to the other. One of these is given, though on doubtful authority, as follows: "There is a large temple, supported by a column, and the column surrounded by twelve cities; each one of these cities has thirty flying buttresses, and near these latter two women, one white and the other black, who measure the extent of them." The temple was the world; the column was a year; the twelve cities were the months, and the flying buttresses, the thirty days; and the two women represented light and darkness, or day and night. Alexander used his sword to save his brains, in cutting the knot with which Gordius, king of Phrygia, had bound the pole of his chariot to the yoke. An oracle had declared that whosoever should untie the knot should reign over

Asia. When he had severed it with his sword, Alexander proceeded to carry out the oracle.

—*Magic Squares.* The ancients ascribed great virtues to magic squares—a name given to a square divided into several small equal cells, filled up with the terms of any progression of numbers, but generally an arithmetical one, in such a manner that those in each band, whether horizontal, vertical, or diagonal, shall always form the same sum. This disposition of numbers formed the basis and principle of many of their talismans. A square of one cell, filled up with unity, was the symbol of the deity, on account of the unity and immutability of God; for they remarked that this square was by its nature unique and immutable. The square of two was the symbol of imperfect matter, on account of the impossibility of arranging this square magically. Magic squares of any size, odd or even, may be formed by classifying all numbers under three different heads, and applying to each separate head a rule peculiar to itself. All numbers come under one of the following classes: 1, all odd numbers; 2, all even numbers that, being divided by 2, give an odd number for a quotient; 3, all even numbers that, being divided by 2, give an even number for a quotient. Before giving the rules for forming squares that come under the above heads, we will give a rule to find the sum of each column in any square, perpendicularly, horizontally, or diagonally: Divide the number of places in one of the parallels plus the cube of the number of places by 2. Thus: 3 by 3 square,

$$\frac{3+3^3}{2} = 15; \text{ 4 by 4 square, } \frac{4+4^3}{2} = 34;$$

$$\text{5 by 5 square, } \frac{5+5^3}{2} = 65. \text{ Examples:}$$

1.					2.							
1	19	7	25	13	24	7	32	8	40	16	48	
10	23	11	4	17	18	43	26	2	34	10	42	
14	2	20	8	21	12	37	20	45	28	4	29	
18	6	24	12	5	6	31	14	39	15	47	23	
22	15	3	16	9	49	25	1	33	9	41	17	
					36	19	44	27	3	35	11	
					30	13	38	21	46	22	5	

$$\text{Sum, } \frac{5+5^3}{2} = 65.$$

$$\text{Sum, } \frac{7+7^3}{2} = 175.$$

I. *Odd-numbered Squares.* Place 1 in any of the small squares; then 2 in the perpendicular adjoining on the right, in any of the small squares, with the exception of the three that are contiguous, horizontally and diagonally to the place in which 1 is contained (the upper and lower parallels, taken together, are always to be treated as if they were contiguous to each other—that is, no two consecutive numbers can be placed in adjoining perpendiculars and in the

upper and lower parallels at the same time); then 3 in the next perpendicular to the right, as before, and at the same horizontal distance from the 2, and in the same direction, that the 2 is from the 1—taking care, however, if counting down, when the lower parallel is reached, to treat it as if it were immediately above the upper, and, *vice versa*, to treat the upper as if it were beneath the lower one, and also, when the extreme right perpendicular is reached, to treat it as if it were placed on the extreme left; and so on until we have set down a number that is an exact multiple of the number of places in one of the parallels; then place the number following in the same horizontal, but the second perpendicular to the right; then place the numbers following the same as with 2 and 3, until a multiple is reached; and so on until the square is completed. The following are some of the properties of the squares formed from this rule: 1. From any of the four sides, beginning with any number, take the numbers diagonally either way from it, and if, before we get the proper number of figures, the diagonal ends in one of the sides, continue on to the first place in an imaginary square adjoining, and take the figure from a similar place in the principal square, and continue diagonally in the same direction as before until we reach the opposite side from which we began, and we find the sum of these numbers equals the sum of each of the columns. For example (from the 5 + 5 and the 7 + 7 squares): $19 + 11 + 8 + 5 + 22 = 19 + 10 + 21 + 12 + 3 = 13 + 10 + 2 + 24 + 16 = 65$; and $49 + 31 + 20 + 2 + 40 + 22 + 11 = 49 + 19 + 38 + 8 + 34 + 4 + 23 = 175$. 2. Suppose we take one or more rows from the top, and place them beneath the lower one in the same order that we find them, or, *vice versa*, from lower to upper, the squares thus resulting will still be magic. 3. If we take one or more of the perpendiculars from the right or left side, and transfer them to the opposite side, we have another square that is magic. 4. For the first row of a new square write the numbers as directed in property 1, above; then, for the first figure in the second row, set down the number in the old square, in the first diagonal, in the opposite direction from the point at which we started to form the first row; then complete it in the same manner; and so on with the remaining rows until the square is completed, and still another magic square is the result. The following, in illustration of the above, are derived from the 5 × 5 square:

3.					4.

Other squares may be derived from these last, in the same manner that they were derived from the first, and these again can be resolved into other squares that are still magic; and so on, without end. This rule holds good for all odd-numbered squares except the 3×3 square. This (and indeed all odd-numbered ones) can be formed by placing unity in the middle cell of the horizontal band at the bottom, then proceeding from left to right, and descending diagonally (overlapping the perpendiculars and horizontals, as shown above). When 3 or a multiple of 3 has been set down, place the following number immediately above it, and continue as before. According to this disposition, the middle number occupies the centre. Examples:

6.

4	9	2
3	5	7
8	1	6

7.

11	18	25	2	9
10	12	19	21	3
4	6	13	20	22
23	5	7	14	16
17	24	1	8	15

II. *Even-numbered Squares*, which, the number of places in any of the parallels being divided by 2, give an odd number for a quotient; as:

8.

3	4	76	78	28	25	100	97	49	50
1	2	74	75	26	27	98	99	51	52

85	86	59	58	11	10	63	62	35	36

$$\text{Sum}, \frac{10+10^3}{2} = 505.$$

VOL. XIV.—56

For the formation of squares coming under this rule, we adopt the same principle that is used in the construction of odd-numbered squares, taking for convenience the rule already given in this article as an example, although any rule under which it is possible to form odd-numbered squares may be used equally well. The $10 + 10$ square is used for the illustration of the process. The first step is to divide the proposed square into sets of four places each by the heavy lines; now, counting the spaces between the heavy lines only, we have a $5 + 5$ square, each place of which is divided into four parts by the fainter lines. Divide the numbers that are to enter into the proposed square into sets of four each, each set containing four consecutive numbers; each set is then to be placed in a square bounded by the heavy lines, and each number in one of the four places into which these are again divided. The first set (1, 2, 3, 4) is to be placed where 1 would be placed according to the rule for odd-numbered squares, the second set (5, 6, 7, 8) where 2 would be placed, and so on. It will be noticed that the four numbers included between the heavy lines are not to be arranged in the same order throughout the whole square. The following is the rule for arranging them in proper order: Divide the square by a perpendicular line into two parts, so that there is one more parallel, counting only between the heavy lines, on the right side than on the left. Then—1, the proper order for all places in the diagonals to the right of this line is, $\frac{1}{3} \mid \frac{2}{4}$; 2, for all places in

the diagonals to the left of the line, $\frac{3}{1} \mid \frac{4}{2}$, 3, for one place on each side of the centre in the middle horizontal, $\frac{4}{3} \mid \frac{2}{1}$; 4, for one place immediately above the centre in the middle perpendicular, $\frac{4}{3} \mid \frac{1}{2}$; 5, for one place immediately below the centre in the middle perpendicular, $\frac{1}{3} \mid \frac{4}{2}$. The above five rules include all the places in a $6 + 6$ square, treated as required by the rule. For all larger squares the following are to be used in addition to the above: 6, for all places in the centre horizontal not mentioned in rules 1 and 3, the same as No. 4; 7, for all places above the centre horizontal not mentioned in the previous rules,

$\frac{4}{2} \mid \frac{1}{3}$; 8, for all places below the centre horizontal not mentioned in the previous rules, the same as No. 5. The square is now completed.

III. *Even-numbered Squares*, which, the number of places in any of the parallels being divided by 2, give an even number for a quotient; as:

9.

9	16	5	4
6	8	10	15
12	13	3	1
7	2	11	14

$$\text{Sum}, \frac{4+4^3}{2} = 34.$$

10.

33	48	49	64	25	24	9	8
26	23	10	7	84	47	50	63
35	46	51	62	27	22	11	6
28	21	12	5	86	45	52	61
40	41	56	57	32	17	16	1
31	18	15	2	39	42	55	53
38	43	54	59	80	19	14	3
29	20	13	4	87	44	53	60

$$\text{Sum}, \frac{8+8^3}{2} = 260.$$

To make the rule more clear, the squares are divided into quarters by the heavy lines. Begin by placing 1 in the upper right-hand corner of the lower right quarter; then go to the horizontal immediately beneath, and place 2 in a similar square in the lower left quarter; and so on downward, from right to left, and *vice versa*, until the lower horizontal is reached; then place the following number in a similar place in the quarter above on the same side; then proceed upward, from left to right, and *vice versa* (in the same manner that we proceeded downward when in the lower half), until the upper horizontal is reached; then the number following all multiples of the number of places in each parallel, if in the right half, to the place adjoining on the left of the multiple—if in the left half, to the right of it. From the upper row proceed downward, as in the lower half,

till you reach the lower horizontal of the upper half; then place the following number in a similar place in the quarter below on the same side; then proceed upward, in the same manner as in the upper half, till the upper horizontal of the lower half is reached; and so on, till you have written half of the figures in the proposed square. The first number of the second half write in the upper left-hand corner, and continue to complete the square in the same manner as before described. Properties 1, 2, and 3, of the odd-numbered squares in this article, are also true of these arrangements.—See “Recreations in Science and Natural Philosophy,” Dr. Hutton’s translation of Montucla’s edition of Ozanam, revised and corrected by Edward Riddle (London, 1851).—*The Anagram*, once popular as an indication of fate or character, serves now only as an amusement, or to devise a motto for a crest. (See ANAGRAM.)—*Conundrums* intend to denote in an obscure form something well known and familiar, and depend for their wit and the concealment of the answer on a play upon words; as, “What is the difference between a honeycomb and a honeymoon?” “One is composed of many little cells, and the other is one big sell.” The art of composing them was much cultivated during the middle ages. Numerous collections of them have been made in all languages. In French, Cotin gathered from everywhere the finest enigmas, under the title of *Recueil des énigmes de ce temps* (1st ed., Paris, 1656; 2d, Rouen, 1673). Menestrier about the same time composed a *Traité de l’énigme*.—*The Ring Puzzle* is of great antiquity; a treatise was written on it by the mathematician Cardan at the beginning of the 16th century. It is composed

FIG. 1.—The Ring Puzzle.

of several rings, fig. 1, strung on a double rod, and fastened to a flat piece of bone or metal by means of wires which pass through the next ring beyond the one they fasten; the problem is to extricate the rod from the rings. To do this, begin by dropping the 1st, then the 3d; in order to take off the 2d, replace the 1st and drop the first two together; then drop the 5th, replace the first two, drop the 1st alone, replace the 3d and then the 1st; drop the first two and the 4th, replace the first two, drop the 1st and 3d, replace the 1st, and drop the first two together. You have then disposed of five rings, and the 7th stands second on the rod, the only position in which a ring can be dropped. Having dropped the 7th, the next step is to get rid of the 6th. In order to do this, the first five must be reconstructed, and then the

first four dropped, so that the 6th may stand second; it is then easily released, but the 5th remains in its stead; this can only be dropped by replacing the 4th, which by this time is done mechanically. Having successively dropped the 5th and the preceding four, the 9th is in position to drop. When you have mastered the principle, the only hindrance to taking off ten or fifteen of these puzzling rings seems to be the shortness of life and the difficulty of remembering whether your aim is to reconstruct or to release a given ring. To take off all the rings in a puzzle of ten, 681 moves are required.—*The Oblong Ring Puzzle* is made by forming a spiral spring with both ends of the wire with which it is formed turned backward and passed through the spiral. One end is left unconnected and free. The other is formed into a

circular part by carrying it to the other end of the spiral, and is there so connected as to form a loophole, through which the two rings tied

FIG. 2.—Oblong Ring Puzzle.

together can be passed; they can then be carried along on the wire and taken off; these two rings can also be passed over the spiral. The two rings linked together must not be crowded through the spiral. The unconnected end passes through every coil in the spiral, and must not be sprung out of its place. The different parts can be used in any way that does not strain any part of the puzzle. If a new string is required, use a fine one, and have it three inches long after being tied. The puzzle is, to pass the rings so that they will hang on the wire with one of the two rings tied together between the two rings linked together, without the string passing through either of the rings, as in fig. 2; but the string must not pass through the ring. To do this, pass the two rings tied together through the spiral, also through the loophole; carry them along on the wire until you reach the unconnected end; then take one of them off, and pass the other back to the circular part, and place it between the two rings linked together. To do this, it must pass through one of them; then draw the string and the other ring through, so that it will hang free between the rings linked together. Hold the puzzle with the spiral at the top and the loophole to the left. Pass the ring that is now free from the wire through the spiral from the right-hand end, following the wire that leads

to the loophole; pass it through the loophole, following the direction of the same wire; then place the two rings linked together, with the other ring between them, to the right-hand end of the spiral; then slip the ring that is between the two linked together through the spiral, so that one end will reach the loophole, and have the string on the end by the loophole; then bring the ring that is free from the wire toward you from the outside and let it drop through the circular part; then carry it around the loophole in the same way, winding the string tightly around the loophole until you have passed the ring through the circular part four times; then carry it to the right-hand end of the spiral, pass it through the spiral, and slip it over the unconnected end; then draw it back and pass it around on the coil forming the spiral, and as you pass it around the string will unwind from around the loophole; pass it through the loophole, also through the spiral, and the rings will be in the desired position.—*Love's Puzzle* consists of two hearts on a cord. A slip-knot of

FIG. 3.—Love's Puzzle.

cord is first put through a puncture in the centre of a long narrow card. On each end a heart (or ring) is strung, and the cords are fastened to either end of the card. The problem is, to get the hearts together on the same loop. To do this, draw the heart A, fig. 3, along the string, through the loop B, until it reaches the back of the centre hole; by means of the cords C and D draw the loop B through the hole and heart, and pass the heart through the two loops that will be formed; then draw the loop back as before, and the heart may easily be passed to its companion.—*Scissors and Cord*. A simple device makes a puzzle with scissors and cord. A slip-knot is put into one handle, and the ends are passed through the other; these are then securely held, while the scissors are

FIG. 4.—Scissors and Cord.

extricated. This is done by passing the noose through the other handle and then completely over the scissors.—*Heart and Ball*. To make the heart-and-ball puzzle, it is only necessary

FIG. 5.—Heart and Ball.

to cut a thin piece of wood into the shape of a heart, make six holes in it, and provide a silk cord, which is to be doubled, and the two ends fastened into a small wooden ball. To play the ball on, pass the loop through the hole 6, fig. 5, from face to back, up through 2, and then through 3, 5, 4, and 1 in succession; then through 2 again, and down the back to 6; bring it through 6 to the face, and pass it over the ball; then draw the loop back again through 6 and 2, and the puzzle is set. To extricate the string from the heart, which constitutes the puzzle, place the heart before you in the position described in fig. 5, and slacken the string by drawing the ball toward the hole 6; loosen the rest of the string, and draw up the loop as far as possible; pass it through the hole 2 down the other side of the heart to 6, through which bring it to the face and pass it over the ball; then draw the loop back again through the same hole, and the ball and string will come off. The length of the string should be in proportion to the size of the heart; if the latter be $2\frac{1}{2}$ inches high, the string when doubled should be about 9 inches long.—*The Card Puzzle* is represented in fig. 6. A is a piece of card with a narrow slip B B divided from its bottom edge, only leaving sufficient at each side to hold it on. A slip of card C C is passed through a piece of clay-pipe stem D and through the slip B B, the two ends E E projecting to keep the stem in place. The puzzle consists in getting the

FIG. 6.—Card Puzzle.

FIG. 6a.

pipe stem off without breaking it, or injuring any part of the puzzle. To do this, you have only to know how the stem was placed in position. The slip C C, E E is cut out of a piece of card in the

shape shown in fig. 6a. The card in fig. 6 must be gently bent at A, to allow the slip in the bottom B B to pass through the pipe stem as in fig. 6b; the detached slip with the square ends is then passed half way through the loop F at the bottom of the stem; it is then pulled through the stem double, by means of the loop of the slip to the card. Upon unbending the card, the puzzle will be complete and appear as in fig. 6.—*A Japanese Puzzle* consists of seven pieces carved in sandalwood, capable of being arranged in hundreds of devices. It is sold with a book giving 336 different designs and a key.—*Solitaire*. This game is played either with 32 pegs on a board with 33 holes, or with marbles in places hollowed out for them. These are arranged as in fig. 7. The 10th hole has no

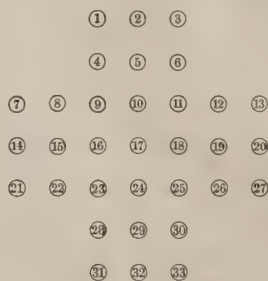

FIG. 7.—Solitaire.

peg, and the game consists in jumping one at a time, at right angles, until only one peg remains on the board, and that in the 10th hole. The first six moves clear off the upper square, and are as follows: 12 to 10, 3 to 11, 10 to 12, 4 to 6, 1 to 3, and 3 to 11. After this you continue in couplets, making ten moves with each hand, going alternately up, across, and down, till you have disposed of all the pegs but six. The ten double moves are: 16 to 4, 18 to 6, up; 13 to 11, 7 to 9, across; 6 to 18, 4 to 16, down; 25 to 11, 23 to 9; 14 to 16, 20 to 18; 11 to 25, 9 to 23; 30 to 18, 28 to 16; 21 to 23, 27 to 25; 16 to 28, 18 to 30; 31 to 23, 33 to 25. The remaining six are arranged in the shape of a cross at the bottom of the board, and are treated as follows: 24 to 22, 32 to 24, 25 to 23, 22 to 24, 24 to 10, the place of beginning.—*Patience*. There are several games of "patience" played with cards; a full account of them can be found in Lady Adelaide Cadogan's "Illustrated Game of Patience."—*Buried Cities* conceal the names of cities in a number of words, the letters coming continuously in their proper order, as: "A cackling hen tells all she knows. Ghent."—*The Rebus* is a picture or series of pictures which represent some proverb, a line of poetry, or a sentence of any kind.—*Enigmas*. The term "enigma" is now generally applied specially to a puzzle which is formed by numbering the letters in one or more words,

FIG. 6b.

so that the letters of other words made from them can be designated. A sufficient number of these latter must be given to bring in every letter of the original word or words at least once, and it must be guessed from them. —The “Fifteen” or “Gem Puzzle,” introduced to the American public in the autumn of 1879, is composed of fifteen small square blocks, numbered from 1 to 15, and contained in a square box large enough to hold sixteen such blocks. The blocks are to be mingled at random, replaced in the box, and pushed about until they are in regular order, as shown on the cover of the box, fig. 8. Out of the 1,307,674,368,000 varieties of chance arrangements which may be given to the numbers in placing

FIG. 8.—Fifteen Puzzle.

them in the box, there are just half in which it is possible, by subsequent movement, to dispose them in regular sequence, in any one of the four ways following: 1, by beginning, as is usual, with the series 1, 2, 3, 4 at the top, and reading from left to right; 2, by beginning with the same series at the bottom, and reading from right to left; 3, by placing this same series on the right-hand side, and reading from the bottom upward; 4, by placing it on the left-hand side, and reading from the top downward. In the remaining cases—half of the whole number possible, or 653,837,184,000—a similar result will be secured by proceeding on any one of these four plans, with the exception that a single couplet in the general series will remain somewhere obstinately inverted. In the usual mode of operating, this inversion commonly appears in the final row, as the fatal 14, 13, 15, or 13, 15, 14; it may also appear as a complete inversion of the triad, 15, 14, 13, which is really a concealed form of the inversion of a couplet; since any one number may be carried past any two preceding or following it without deranging the order of the rest, though no single number can be carried beyond a single neighboring number without produ-

cing an inversion somewhere else. Accordingly, whenever this state of things presents itself, what the operator has to do is, to invert the order of the entire series; that is to say, if he begins at the top, to read from right to left; if he begins at the bottom, to read from left to right; if he begins on the right-hand side, to read from the top downward; if he begins on the left-hand side, to read from the bottom upward. The numbers will then fall easily into their places, and the sequence will be perfect. No particular rules of movement are needed.

QUARTLEY, Arthur, an American painter, born in Paris, France, in 1839. He is entirely self-taught, and has been especially successful as a marine painter. After residing for some time in Baltimore, he settled in New York in 1875. His pictures include “Calm Days, Isles of Shoals,” “Evening at Narragansett,” “Low Tide,” “Making the Landing, White Island, Isles of Shoals,” “Morning Effect, North River,” “An Afternoon in August, Coast of Maine,” and “Morning Effect in New York Harbor.”

RADIOPHONY. The investigations of Messrs. A. Graham Bell and Sumner Tainter, which resulted in the invention of the phonograph, revealed the fact that thin disks of many different substances could be made to emit sounds by exposure to the action of a rapidly interrupted beam of sunlight. Continuing their experiments, these gentlemen found that audible sounds could be produced under similar action from the same substances in masses; and further, that by exposing them in a glass test-tube in immediate communication with a hearing-tube, other substances that could not be obtained in the shape of thin diaphragms or in tubular form, could be made sonorous. In this manner sounds were obtained from various crystalline bodies, from tobacco-smoke and gases, and from cotton-wool, worsted, silk, and fibrous materials generally. Substances of the latter class were found to be the most effective; and the fact was established that the loudest sounds are produced from substances in a loose, spongy condition, and from those that have the darkest or most absorbent colors. Feeble sounds were also obtained from a few liquids. Further experiments were made to test the general proposition that sonorousness, under the effect of intermittent light, is a property common to all matter. Collateral independent investigations of these phenomena have been carried on by M. Mercadier in France, Prof. Tyndall and W. H. Preece in England, and Mr. W. E. Röntgen, the conclusions of which generally tend to confirm this view. Prof. Tyndall found from experiments made with the electric light and the lime light

upon different gases and vapors, that the intensity of the sounds produced was dependent upon the absorptive power of the various bodies. The loudest sounds were obtained from the most athermanous bodies, while diathermanous substances yielded only faint sounds.

Messrs. Bell and Tainter also found that the sonorous effects were due to those rays of the spectrum only which are absorbed by the body. This view was tested by M. Mercadier by passing an intermittent beam from an electric lamp through a prism, and by Messrs. Bell and Tainter with sunlight and a prism, but with somewhat different results from those obtained by M. Mercadier. The experiment of Messrs. Bell and Tainter is illustrated in the diagram, fig. 1. A beam of sunlight was reflected from a heliostat, A, through an achromatic lens, B, so as to form an image of the sun on the slit, C. The beam then passed through another achromatic lens, D, and through a bisulphide-of-carbon prism, E, and formed a spectrum of great intensity, which, when focussed upon a screen, was found to be pure enough to show the principal absorption

G, which was so arranged that the lamp-black surface exposed was limited by a slit, as shown. Under these circumstances, with lampblack, sounds were obtained in every part of the visible spectrum except the extreme half of the violet, and also in the ultra red. With some substances, among them lampblack, the loudest sounds were obtained in the ultra red. No clearly established results were obtained in the ultra violet. The localization of the loudest sounds varied with different substances, and the experimenters were led to the conclusion that the nature of the rays which produce sonorous effects in different bodies depends upon the nature of the substances exposed to the beam, or upon the rays that they have the quality of absorbing. The discovery of these phenomena led Messrs. Bell and Tainter to the construction of a new instrument for use in spectral analysis, which they call the spectrophone, with the aid of which, by noting the bands of sound and silence in the ultra red region, a map of the invisible portion of the spectrum for different substances can be constructed. The eye-piece of a spectroscope is removed, and sensitive substances are placed in the focal point of the instrument behind an opaque diaphragm containing a slit. These substances are put in communication with the ear by means of a hearing-tube. If, then, a rapidly interrupted beam of light is passed through some substance whose absorption spectrum is to be investigated, bands of sound and silence are observed on exploring the spectrum, the silent positions corresponding to the absorption bands. The range of audibility of a number of different substances is indicated in fig. 2 by the rectangular figures in black enclosing their names. Of course the ear cannot compete with the eye in the examination of the visible part of the spectrum; but in the invisible part, beyond the red, where the eye is useless, the ear is invaluable. Mr. Bell believes that the sounds are produced by the alternate expansion and contraction, under the intermittent rays, of the air contained in the bodies experimented upon, operating to produce a continuous series of atmospheric pulsations. Prof. Tyndall concludes that the tones given out by the gases he experimented upon were the result of their rapid successive dilatations under the influence of the heat. Mercadier has obtained tones from the red and heat rays, and from the heat rays alone; and Tyndall produced sounds by placing a piece of iron not quite red-hot behind the interrupting disk. The words "light" and "photophone," which were at first used in describing these experiments, only in the most general sense, because the ordinary beam of light contains the rays which were operative, convey an inaccurate impression by seeming to ascribe to light actions which may be due to any form of radiant force, whether thermal, luminous, or actinic. M. Mercadier has suggested, and the other experimenters have adopted, the more accurate term "radiophone," to signify gener-

FIG. 1.

lines of the solar spectrum. The disk interrupter, F, was then turned with sufficient rapidity to produce from five to six hundred interruptions of the light per second, and the spectrum was explored with the receiver,

ical and explanatory, of the Old Testament, and the first volume, containing Genesis, was published in 1844.

RASSAM, Hormuzd, a British archæologist, born at Mosul, Mesopotamia, about 1828. He is descended from a Chaldean or Assyrian family which was included among the earliest Christian converts. When in 1847 Mr. Layard returned from his researches among the ruins of Nineveh, he brought with him Mr. Rassam, who had learned English from his brother's wife, a sister of the Rev. George Percy Badger, the Arabic scholar, and who had for two years been the explorer's companion. The young man entered Oxford, but in 1849 was appointed by the trustees of the British museum to return to Nineveh with Mr. Layard in order to make further investigations, which proved very successful. Coming back to England in 1851, Mr. Rassam was again sent out by the museum authorities, this time in place of Mr. Layard, and procured many valuable antiquities. Returning in 1854, he was made interpreter to the political resident's staff at Aden, and afterward assistant political resident. In 1864 he was despatched with a message from the queen to King Theodore of Abyssinia, in relation to the latter's imprisonment of the consul Cameron. He arrived at Massowah in July of the same year, but was not allowed to discharge his errand until January, 1866; and finally, when on the point of departure with the liberated captives, he was arrested, and with them kept in fetters from July, 1866, till March, 1868, just before Magdala was stormed by Lord Napier. In 1876 he was sent out by the British museum to effect certain Assyrian explorations, under a firman of the Turkish government. His discoveries were very important, and among the prizes which he brought back to England was a pair of bronze gates, 22 feet high, a memorial of the wars of Shalmaneser III., B. C. 850, which he found in the ruins of a suburban palace near Kalakli. He was also employed upon political missions in Armenia and Kurdistan, and in 1878 was sent, under another firman, upon a new exploring expedition to northern Syria, Assyria, and Babylonia, being especially fitted for such work by his vast acquaintance with oriental languages. He has published a "Narrative of the British Mission to Theodore, King of Abyssinia; with Notices of the Country traversed from Massowah, through the Soudân, the Amhâra, and back to Annesley Bay from Magdala" (2 vols., London, 1869).

RAYMOND, John T., an American actor, born in Buffalo, N. Y., April 5, 1836. He was placed in a counting house, but ran away from it at the age of 17, and appeared on the stage at the Rochester theatre, making his début as Lopez in "The Honeymoon." The attempt was a failure, but the managers, who thought they discovered comedy talent in him, kept him through the season. The next year (1854) he appeared at Niblo's Garden, New York, in

"Ingomar," and in 1855 entered upon a long engagement in Baltimore. After its close he played in most of the southern cities, appearing at Charleston as Asa Trenchard in "Our American Cousin," with Sothern as Dundreary. In 1861-'3 he played at Laura Keane's theatre in New York, his most noticeable part being that of Baby in "Peep o' Day." After travelling two or three years with a company of his own in Maryland and West Virginia, he went to London in the summer of 1867, and appeared at the Haymarket as Asa Trenchard, with Sothern, making a great success. After the withdrawal of the piece, he made a starring tour through the provinces, and returned to America, appearing at the Theatre Comique, New York, as Toby Twinkle in "All that Glitters is not Gold." He played for two seasons in San Francisco, returned to New York in 1871, and appeared at Booth's theatre and at the Globe, Boston, as Dick Swiveller and Wilkins Micawber. But his final and greatest success was when, in 1874, he brought out at the Park theatre, New York, "The Gilded Age," a dramatization of the novel of that name written by "Mark Twain" and Charles Dudley Warner. In this Mr. Raymond took the part of Col. Mulberry Sellers, which he made peculiarly his own, and which soon overshadowed everything else in the play. He went to England on a professional engagement in the summer of 1880; but his rôle of Col. Sellers did not prove popular there, and he soon returned.

REGNAULT, Alexandre Georges Henri, a French painter, born in Paris in 1843, died in the defence of Paris, Jan. 19, 1871. His father was director of the manufactory at Sèvres. His first master was a pupil of Hippolyte Flandrin, whose cold tones and formal manner were directly antagonistic to the sensuous luxuriance that distinguishes the works of Regnault, and makes him the chief representative of the realistic and coloristic movement of recent French art, which confines the interest of a painting to simple form and color, degrades human figures to the office of conveying purely æsthetic impressions, and places them in the same category with animals or flowers, or the rich stuffs with which the artists of this school delight to fill their pictures. Regnault's true tendencies were developed in the atelier of Cabanel. At the age of 23 he won the grand prize of Rome with his "Thetis bringing the Arms of Achilles." In search of a new field for the picturesque, he visited Morocco. His picture of "Salome," exhibited in 1869, created a profound sensation in Paris. Among his most admired works are his portraits and sketches of portraits. A volume of his correspondence was published in 1873.

REINHART, Benjamin Franklin, an American painter, born near Waynesburg, Pa., in 1829. After very little instruction, he began life as a portrait painter, but afterward studied in New York, Düsseldorf, and Paris. On the breaking out of the civil war he went to Lon-

don, where he spent seven years in painting English genre subjects. In 1868 he settled in New York. His works include "Cleopatra," "Evangeline," "The Nymphs of the Wood," "Katrina Van Tassel," "Pocahontas," "Washington receiving News of Arnold's Treason," "Young Franklin and Sir William Keith," "The Pride of the Village," and numerous portraits of celebrated persons. Many of his pictures have been engraved.

REINHART, Charles S., an American artist, born in Pittsburgh, Pa., in 1844. After spending three years in the military service during the civil war, and four years in a steel manufactory at Pittsburgh, he studied art in Europe and settled in New York. His pictures in oil include "Caught Napping," "Clearing Up," "Reconnoitring," and "The Rebuke;" in water-color, "The Close of Day," "Gathering Wood," "At the Ferry," "No Trespassing," and "Noon and Midnight." The greater part of his art work has been devoted to the illustration of books.

REPOUSSÉ (Fr., beaten back), a process of working in metals, by driving out the design by means of beating on the reverse side. The art is of great antiquity, and was practised by the Egyptians, Cypriotes, and Etruscans. Some very beautiful examples of Etruscan repoussé work were on exhibition in the Castellani collection at Philadelphia in 1876. The art has flourished in Europe during the past three centuries. Benvenuto Cellini was a master in it, and was employed by popes, kings, and other princely patrons. It was said that he could work an ounce of silver into such exquisite form as to make golden ducats contemptible in comparison. The system is now used extensively in the United States, as well as in Europe, for decorating silver. The Bryant vase, made by Tiffany and co., and now in the metropolitan museum of art, New York, is an exquisite specimen of this process. When a bowl is to be wrought in the repoussé mode, it is first beaten into the required shape, and then given into the hands of the decorator. Upon its perfectly smooth surface is traced the design. Then the "snarling iron" comes into requisition. The end A of this is securely fastened in

a vise; the end C is placed on the inner side of the bowl in contact with that part of the decoration that is intended to be in relief; and the part B, near the vise, is skilfully struck with a mallet. The vibration of the iron drives out the silver without weakening it. The effect of the blow varies, according to the spot struck; the further from the vise, the more abrupt the shock. Snarling irons vary in length from 6 to 18 in., and in width from half an inch to an inch and a half. After the whole

design has been rounded out from within, the bowl is filled with a composition of plaster, pitch, and oil, and given into the hands of the engraver, who sits at a table with two or more sand bags (upon which he lays the bowl), a light mallet, and innumerable small tools, about 5 in. long, and fashioned at the end in every conceivable shape—sharp for engraving, blunt for planishing, and honeycombed for some of the backgrounds of the many exquisite designs. Points that are no larger than a pin's head have six perfect little cells in them, only discernible with a microscope. With 1,700 different tools, which at a glance might be mistaken for a box of nails, a workman complains that he has not half enough. And yet a finished piece of repoussé work, with its clear, sharp outline, suggests no thought of snarling iron, mallet, or engraver's tools.

REUTER, Baron Paul Julius, founder of the "Reuter Telegraphic Agency," born in Cassel, July 21, 1821. While employed in a bank at Göttingen, he spent his spare hours in reading the works of Gauss on electro-magnetism. In 1847 he became connected with a bookstore in Berlin, which was ruined by the revolution of the next year. He then went to Paris, and established a bureau for furnishing the newspapers with information by means of the lithographic process. In October, 1849, the Prussian government having opened to the public the first European telegraph line between Aix-la-Chapelle and Berlin, Reuter established in the former city a telegraphic news agency, which was enlarged as new lines of wire were opened, carrier pigeons being also employed. When, in 1851, the cable was laid between Calais and Dover, he established his headquarters in London, was naturalized as an Englishman, and proceeded to set up agencies in all parts of the world for the collection and transmission of commercial and political news. The system at once began to enjoy the favor of business men, but was adopted more reluctantly by the great newspapers. By furnishing all the journals that he served with the same news, Mr. Reuter was enabled to offer such low rates as to assist greatly in the development of cheap newspapers. During the American civil war and the Franco-German war he succeeded in providing the journals with accurate news of important events ahead of the official reports. In 1865 the business was transferred to a stock company, of which Mr. Reuter remained the manager. In that year he was awarded by the government of Hanover a concession for laying a cable between England and Germany, and in 1868 one by France for the first line between that country and the United States, which was opened in 1869. In 1871 he received the title of baron from the duke of Coburg-Gotha. The next year he obtained a concession of enormous powers from the shah of Persia, granting him the exclusive privilege of building railroads, working mines and forests, and farming the customs of the kingdom; but in his at-

tempt to take advantage of this great monopoly, he met with serious obstacles.

RHAMNUS PURSHIANA, a shrub or small tree, related to the buckthorn, 10 to 20 ft. high, the bark of which has been introduced into medicine within a few years, under the name *cascara sagrada*. It grows on the Pacific coast. Its medicinal properties are quite similar to those of other species of *rhamnus*. In small doses it is laxative; in large doses, cathartic. The fluid extract is the preparation generally employed. It may be given in doses of from 15 to 60 drops, according to the effect desired.

RHODE ISLAND. The population of the state in 1880 was 276,531, of whom 133,030 were males, 143,501 females, 202,538 natives, 73,993 foreign, 269,939 whites, 6,582 colored. The chief agricultural productions were 17,783 bushels of barley, 372,967 of corn, 159,339 of oats, 12,997 of rye, 79,328 tons of hay, 606,793 bushels of potatoes; number of horses on farms, 9,661; 3,523 working oxen, 21,460 milch cows, 10,601 other cattle, 17,211 sheep, 14,121 swine; value of manufactures, \$104,163,621. The state debt on Dec. 31, 1881, amounted to \$2,521,500; at the same date in 1882 it was \$1,606,500. The receipts and expenditures during 1882 were as follows:

Receipts	\$888,419 34
Balance in the treasury Dec. 31, 1881	210,789 90
Total	\$1,099,209 24
Expenditures	774,289 80
Balance in the treasury, Jan. 1, 1883	\$324,919 44

The deposits in the savings banks, on the 28th of November, 1882, amounted to \$50,657,876 80, including \$187,067 49 of surplus profits on hand; which shows in the deposits an increase of \$1,548,948 37 over those of 1881. The whole number of depositors in November, 1882, was 112,472, showing an increase of 9,481 over the preceding year.—The following educational statistics are for 1881: number of children from 5 to 15 years enumerated, 53,077; number of children reported attending public schools, 33,930; Catholic schools, 4,723; select schools, 1,994; no school, 12,730; total receipts, \$582,965 19; current expenditures, \$499,102 71; permanent expenditures, \$50,833 97. The charitable, reformatory, and penal institutions supported by the state are grouped together at Cranston, on "the state farm." The number of these institutions and of their inmates, on Dec. 31, 1882, was as follows: Asylum for the insane, 305; workhouse and house of correction, 252; almshouse, 221; Sockanosset school for boys, 188; Oaklawn school for girls, 24; state prison, 94; and Providence county jail, 129; in all, 1,163. The governor states the increase in the number of insane persons at the asylum to have been alarming for several years, and that in 1882 this increase was two thirds larger than in 1881, the insane patients reported at the close of the said two years having been 303 and 281 respectively.—The railway lines transacted during 1882 a considerably larger amount of busi-

ness than during the previous year: the total number of passengers in 1882 having increased to 3,822,220, and that of tons of merchandise to 672,391. But their general expenses have so far increased that in their net earnings there has been a decrease of \$244,869 75.—The population of the principal places, by the census of 1880, was: Providence, 104,857; Pawtucket, 19,030; Woonsocket, 16,050; Newport, 15,693; Lincoln, 13,765; Warwick, 12,164. See map in supplement to Volume V.

RICHARDS, Brinley, a British musician, born in Carmarthen, Wales, in 1819. His father was an organist. He was educated at the royal academy of music, where he gained a scholarship. He ranks high as a pianist, but is especially known as a composer of Welsh national songs. Among these are "Cambrian War Song," "The Cambrian Plume," and "The Harp of Wales." His sacred songs include "In the hour of my distress," "The pilgrim's path," "As o'er the past," and "Through the day;" and his part songs, "Up, quit thy bower!" "What bells are those?" "Sweet day, so cool," and "Ye little birds." He has also published piano and orchestral music.

RICHARDS, Thomas Addison, an American painter, born in London in 1820. His parents emigrated to Georgia when he was a boy, and he settled in New York in 1845. From 1858 to 1860 he was director of the Cooper union school of design for women, and since 1867 he has been professor of art in the university of New York. He was elected an associate of the national academy of design in 1849, and an academician in 1851, and has been corresponding secretary since 1852. Among his best works are "Alastor, or the Spirit of Solitude," "The Indian Paradise," "Edisto River," "French Broad River," "Live Oaks of the South," "The Rhine," "Warwick Castle," "Chatsworth, England," "Lake Thun, Switzerland," "Lake Winnipiseogee," and "Sunnyside." He has contributed many pictorial papers to the magazines, and has illustrated numerous books. One hundred of his pictures were exhibited and sold in New York in 1871. He was the author at an early age of a text-book on painting entitled "The American Artist." In 1842 he made the drawings for "Georgia Illustrated," and subsequently published "The Romance of American Landscape" and "Pictures and Painters;" and for several years he was the American correspondent of the London "Art Journal."

RICHARDS, William T., an American painter, born in Philadelphia in 1833. He studied in Rome, Florence, and Paris, and in 1856 opened a studio in his native city. His works in oil include "The New England Coast," "Atlantic City," "Mid-Ocean," "June Woods," "Midsummer," "Ebb Tide," "Old Orchards at Newport," "The Wissahickon," and "Out in the Country;" in water-color, "Mount Desert," "Off the Spar Buoy, Atlantic City," "Lake Squam," "The Third Beach, Newport," "So-

west Point, Canonicut," and "Gooseberry Island, near Newport."

RIPLEY, George, an American scholar, born in Greenfield, Mass., Oct. 3, 1802, died in New York city, July 4, 1880. He was the youngest son of Jerome Ripley, a merchant, from whom he inherited a moderate fortune. He was fitted for college by his kinswoman, Margaret Ripley of Concord, graduated at Harvard in 1823, and three years later at the Cambridge divinity school. In 1825-'6 he was a mathematical tutor in the university. From 1828 till 1841 he was pastor of the Purchase street (Unitarian) church in Boston. He was an intimate friend of Theodore Parker, and apart from his clerical duties devoted himself especially to the study of philosophy, and also became exceedingly familiar with German theology and biblical criticism. In the great philosophical controversy which prevailed in Boston in 1837 till about 1845, he took part against the school of Locke and Paley. With a view to promote the transcendental or spiritual conception of the soul and its relations he commenced the publication of "Specimens of Foreign Literature" (14 vols., Boston, 1838-'42), and himself translated the first two volumes of the series, selecting his material from the writings of Cousin, Jouffroy, and Constant. This work, which he called "Philosophical Miscellanies," was enriched by an elaborate introduction from his pen, and was republished in Edinburgh in 1857. In 1839 Mr. Ripley became still more conspicuous through a controversy with Prof. Andrews Norton of the Harvard divinity school, in which, in two public letters, he explained the philosophy and theology of Spinoza, Schleiermacher, and De Wette, and defended them against the imputations of that theologian ("Letters to Andrews Norton on the Latest Form of Infidelity," Boston, 1840). He was associated with Ralph Waldo Emerson and Margaret Fuller in the editorship of "The Dial" in 1840-'41, and also contributed largely to the "Christian Examiner" and other periodicals. He founded the "Brook Farm Association of Education and Agriculture," in West Roxbury, Mass., in 1841, and was its president till the dissolution of the association in 1847. Hawthorne, who for a short time was connected with it, used it as the occasion of his "Blithedale Romance;" but no authentic history of the experiment has ever been published. According to its constitution, it was intended "more effectually to promote the great purposes of human culture, to establish the external relations of life on a basis of wisdom and purity, and to substitute a system of brotherly coöperation for one of selfish competition." The association had about 70 members, who cultivated a farm, taught pupils, and published "The Harbinger" (1845-'9), edited by Mr. Ripley with John S. Dwight and Charles A. Dana, which advocated the doctrines of Fourier. In 1849 he became the literary critic of the New York "Tribune," which post he held till his death. He was also for several years a regular

writer for the critical department of "Harper's Magazine." With Bayard Taylor, he edited "A Handbook of Literature and the Fine Arts" (New York, 1852). In 1856 Mr. Charles A. Dana, having undertaken the editorship of the "New American Cyclopædia," invited Mr. Ripley to join him in the enterprise. The first volume of the work was published in 1858, and the last in 1863. In 1869 Mr. Ripley visited Europe, where he travelled extensively and wrote a series of letters for publication. After his return the revised edition of the Cyclopædia was commenced under a modified title, the first volume of which appeared in 1873, and the last in 1876. In 1874 he received the degree of LL. D. from St. Lawrence university. He was twice married: first to Sophia W. Dana, who died in 1861; and in 1865 to Mrs. Louisa A. Schlossberger, who survived him.

RIVIERE, Briton, an English painter, born in London, Aug. 14, 1840. He studied with his father, who was a teacher of drawing, and afterward graduated in the classical course at Oxford. He is especially distinguished as an animal painter. Among his pictures are "Rest from Labor," "Sheep on the Cotswolds," "On the Road to Gloucester Fair," "Iron Boys," "Romeo and Juliet," "The Poacher's Nurse," "Strayed from the Flock," "The Long Sleep," "Fox and Geese," "Circe transforming the Friends of Ulysses into Pigs," "War Time," "The Last of the Garrison," "All that was left of the Homeward-bound," "A Stern Chase is always a Long Chase," and "A Legend of St. Patrick."

ROE, Edward Payson, an American author, born in New Windsor, N. Y., in 1838. His early home is described in his "Opening of a Chestnut Burr." He studied at Williams college and at Auburn theological seminary, and in 1862 became chaplain of the 2d New York cavalry. He rode as a volunteer in Dahlgren's raid within the defences of Richmond, in the spring of 1864. Subsequently he was a chaplain in the hospitals at Fortress Monroe. After the war he became pastor of the Presbyterian church at Highland Falls, N. Y., near West Point, and delivered lectures on topics connected with the civil war. After walking through the smoking ruins of Chicago, he began his novel "Barriers Burned Away," which was published as a serial in the New York "Evangelist," and appeared in book form in 1872. Of a cheap edition (1882) 87,500 copies were sold. The great success of this book, together with impaired health from pastoral work, induced Mr. Roe to give up preaching and settle at Cornwall-on-the-Hudson in 1874, where he has since given his time to literature and the cultivation of small fruits. His subsequent novels, all of which have had a wide circulation, are: "What Can She Do?" (1873); "The Opening of a Chestnut Burr" (1874); "Near to Nature's Heart" (1875); "From Jest to Earnest" (1876); "A Knight

of the Nineteenth Century" (1877); "A Face Illumined" (1878); "A Day of Fate" (1880); and "Without a Home" (1881). He has also published "Play and Profit in my Garden" (1873), "The Culture of Small Fruits" (1876), and "Success with Small Fruits" (1880). His novels have been republished in England, and are in course of translation into German.

ROON, Albrecht Theodor Emil, count von, a German soldier and statesman, born at Pleushagen, near Colberg, April 30, 1803, died Feb. 23, 1879. He was educated at the Berlin barracks, became a second lieutenant in 1819, and studied at the military academy from 1825 to 1827. In 1828 he was appointed a teacher of cadets. In 1833 and 1834 he was engaged in topographical work, and in 1835 was attached to the general staff. From 1838 to 1841 he was an instructor in the military academy. In 1843 he joined the general staff, and was made military instructor to Prince Frederick Charles, and afterward his military governor, accompanying him in his journeys through Switzerland, Italy, France, and Belgium. After the education of the prince was completed, Major von Roon became in 1848 chief of staff to the 8th army corps in Rhenish Prussia; and in 1849 he took part in the Baden campaign as chief of staff to Gen. Hirschfeld. He became in 1856 a major general, commanding the 14th division at Düsseldorf. Having won the favor of the prince regent (the present emperor) by his efforts to effect certain reforms in the Prussian military organization, he was in 1859 made a lieutenant general, and the same year was appointed minister of war. The portfolio of marine affairs was added to his charge in 1861. In spite of the opposition of the diet, he succeeded in reorganizing the army, and the fruits of his ability and energy were reaped in the Prussian successes in the Schleswig-Holstein campaign of 1864 and the Austrian war of 1866, in the latter of which Von Roon participated in the field. The result of the Franco-Prussian war shed more glories upon his wonderful powers as an organizer, and in 1871 he was made a count. In that year he resigned the ministry of marine, and in 1872, his conservative policy being in conflict with that of Bismarck, he gave up the war portfolio, but was at once made president of the council, and at the beginning of 1873 a field marshal. In the following November, in order that Prince Bismarck might unite in his own person the offices of chancellor and president of the council, Von Roon left the cabinet and retired to his estates. He wrote *Grundzüge der Erd-, Völker- und Staatenkunde* (1832; 3d ed., in 3 vols., 1847-'55), *Militärische Länderbeschreibung von Europa* (1837), and other valuable works.

ROSS-CHURCH, Florence Marryat, an English authoress, born in Brighton, July 9, 1837. She is a daughter of Capt. Frederick Marryat, the novelist. She was educated mainly at home, and in 1872 became editor of "London Society." Her novels, some of which have been

translated into several of the continental languages, include "Love's Conflict" and "Too Good for Him" (1865); "Woman against Woman" and "For Ever and Ever" (1866); "Confessions of Gerald Estcourt" and "Nelly Brooke" (1867); "Girls of Feversham" and "Veronica" (1868); "Petronel" (1869); "Her Lord and Master" (1870); "The Prey of the Gods" (1871); "Mad Dumaresq" and "No Valentines" (1873); "A Little Stepson" (1877); and "Her Word against a Lie" (1878). She has also published her father's "Life and Letters" (1872).

ROSSETTI, William Michael, an English author, son of Gabriele Rossetti, born in London, Sept. 25, 1829. He was educated at King's college school, London, was appointed in 1845 to a clerkship in the excise office, and in 1869 became assistant secretary there. He was active in the pre-Raphaelite movement begun in 1848, and wrote for "The Germ," the magazine that represented it. Subsequently he was fine-art critic for several periodicals in succession. He has published a very literal translation, in blank verse, of Dante's "Hell" (1865); "Fine Art, chiefly Contemporary" (1867); "Mrs Holmes Grey," a poem (1870); and "Lives of Famous Poets" (1878); and has edited a series of "Popular Poets" (1870-'75), and the poems of Shelley, William Blake, and Walt Whitman. He has also lectured on Shelley's life and works. In 1874 he married a daughter of Ford Madox Brown, the painter, who is herself an artist.

RUSSELL, Charles William, an Irish historian, born in the County Down, Ireland, in 1812, died March 26, 1880. He was educated at Maynooth college, and in 1857 was made president of that institution. He was appointed a member of the royal commission on historical manuscripts in 1869, and edited, with Mr. Pendergast, several volumes of the state papers relating to Ireland, beginning with the reign of James I. He published a translation from the German of the tales of Canon von Schmidt (3 vols., 1846), and Leibnitz's "System of Theology," with introduction and notes (1850). His chief work, "The Life of Cardinal Mezzofanti" (1858), was translated into Italian (Bologna, 1859). The second edition (1863) was augmented by ten fac-simile autographs of the cardinal, in different languages.

RUSSO-TURKISH WAR. In July, 1875, the people of the Christian province of Herzegovina, European Turkey, rose in rebellion against their Turkish masters. The direct cause of the movement is variously stated as having been the exactions of the tax-gatherers and the brutal treatment of two Christian women, following the visit of the emperor of Austria to Dalmatia, which naturally suggested to the Herzegovinians a comparison of their own condition with that of their brethren over the Austrian border. The revolt soon spread to Bosnia, and, aided by volunteers from Montenegro and Servia, the insurrectionists under

Liubibratitch and Peko Pavlovitch successfully withstood such forces as were sent against them. The Turkish government was profuse in its promises of reforms, but the insurrectionists put no confidence in them. In January, 1876, a circular drawn up by Count Andrassy, the Austrian chancellor, and endorsed by Russia, England, Germany, France, and Italy, was submitted to the Porte, demanding complete religious liberty, the abolition of the farming of the revenue, application of the direct taxes to local improvements, creation of a mixed commission to oversee the reforms, and amelioration of the condition of the agricultural population. On Feb. 11 the sultan issued a decree promising complete religious liberty, reform in the taxation, sale of waste lands to the needy, mixed commissions to oversee reforms, and an increase of the sums devoted to local improvements. The insurrectionists refused these terms, and demanded an independence like that of Montenegro. In April they submitted certain proposals as a basis for a suspension of hostilities, among which were the confinement of the Turkish troops to six fortresses, permission to retain their own arms until the Mohammedans had surrendered theirs, the suspension of taxes for three years, the leasing of one third of the lands occupied by the Christians to their cultivators, the immediate execution in those portions of Bosnia not in revolt of the reforms suggested by the Andrassy note, and the appointment by the great powers of a commission to oversee the reforms. Hostilities were suspended, but soon broke out again, and the Turks were enabled to provision their garrisons in Herzegovina only after severe fighting and heavy losses. On May 7, during a riot in Salonica, caused by the abduction of a Bulgarian girl by a Turkish official, the French and German consuls were massacred by a mob. Their families were paid a large indemnity by the Porte, but the punishment inflicted upon the ringleaders of the mob was pronounced insufficient by the governments outraged. The chancellors of Russia, Germany, and Austria met at Berlin, and formulated the Gortchakoff note or Berlin memorandum, declaring that Turkey had virtually pledged herself to carry out the reforms called for by the Andrassy note, that she had failed to do so, and that the Salonica outrage showed the powerlessness of the sultan to restrain his subjects. It demanded an armistice of two months on the basis of the Andrassy note, during which the Porte must reach an adjustment of its relations with the provinces in insurrection, or it would become necessary for the great powers to take effective measures to preserve the peace. France and Italy gave in their adhesion to this note, but England refused to concur, on the ground that it must inevitably lead to the military occupation of Turkey, and sent a fleet to Besika bay, at the southern end of the Dardanelles. In the night of May 30-31 the sultan Abdul-Aziz was deposed by a palace conspiracy,

and was succeeded by Prince Murad Effendi, eldest son of the late sultan Abdul-Medjid, as Murad V. An insurrection which had broken out among the Christian inhabitants of Bulgaria was stamped out during May, with circumstances of great atrocity, by the bashi-bazouks (Turkish irregulars) and Circassians, colonies of whom, emigrating from Russian rule in their homes, had been planted in Bulgaria. Gradually, partially through the efforts of Mr. McGahan, an American journalist, and Mr. Eugene Schuyler, American secretary of legation at Constantinople, the facts became known in Europe, and excited such popular indignation that the English government informed its minister at Constantinople that, in case Russia made war, Great Britain would find it practically impossible to interfere in defence of Turkey.—In the mean time the governments of Serbia and Montenegro had found themselves no longer able to restrain the zeal of their people to aid the insurgents, and on July 2 declared war against Turkey. Many Russian volunteers joined the Servians, and one of them, Gen. Tchernayeff, commanded the chief of the four armies that now invaded Turkish territory. The Servians, however, were at once driven back on the Timok and on the Ibar, and offensive operations on their part came to an end in a few days. Tchernayeff's army in the south, after falling back within the Servian boundaries, endured six days of hard fighting about the stronghold of Alexinatz, in the latter part of August, with such results as to induce the Servian government to ask for the mediation of the powers. The terms of peace offered by the Porte required the rendering of homage at Constantinople by the prince of Serbia, the reoccupation by the Turks of the Servian fortresses surrendered in 1867, the dismantling of other fortresses, the reduction of the Servian army, the increase of the Servian tribute, a Turkish railway across the country, and the *status quo* for Montenegro, where the success of the fighting had been all on the side of the valiant mountaineers. The powers paid no attention to these terms, but offered as counter-propositions self-government for Bosnia and Herzegovina, a Christian governor for Bulgaria, a port for Montenegro, and the *status quo* for Serbia, except that she should pay a war indemnity. Meanwhile the sultan Murad had been deposed on Aug. 31, on the ground of mental incapacity, and succeeded by his brother Abdul-Hamid II. Fighting was renewed in Serbia at the end of September, but Gen. Tchernayeff's lines were broken at Junis on Oct. 29, and two days later the Turks entered Alexinatz. Russia then presented to Turkey an ultimatum, demanding an immediate suspension of hostilities, and the Porte complied. The Montenegrins had almost entirely cleared their own territory of Turks, and occupied adjoining portions of Albania and Herzegovina. On Nov. 4 the English government suggested a conference at Constantinople, to be composed

of two representatives of each of the great powers, as well as of Turkey. The basis suggested for the conference included the independence and territorial integrity of Turkey; a declaration that none of the powers sought territorial advantages or exclusive influence; the *status quo*, speaking roughly, for Serbia and Montenegro; a system of administrative autonomy for Bosnia and Herzegovina; guarantees of a similar kind against maladministration in Bulgaria; and the execution of the Porte's promised reforms. There was to be no question of the erection of a tributary state. The powers finally agreed to the conference plan. The definite conference began its sessions on Dec. 23, and on the same day Midhat Pasha, the grand vizier, promulgated a Turkish constitution after the West-European model. The final proposals of the conference were confined to a small addition to the Montenegrin territory; peace with Serbia on the *status quo* basis; the nomination by the Porte, in concert with the powers, of governors general for Herzegovina, Bosnia, and Bulgaria; and the appointment by the powers of two commissioners to superintend the reforms. But, as it had been announced that England would in no contingency coerce Turkey, the minimized proposals of the conference were refused by the Turkish government on Jan. 18, 1877, and the conference broke up. The Porte made peace with Serbia, but Montenegro held out for terms that were unacceptable at Constantinople. Subsequently Russia proposed that the powers should unite to sign a public declaration setting forth their demands upon Turkey; and on March 31 a protocol was signed at London by representatives of Russia, Germany, Austria, France, Italy, and Great Britain, announcing the intention of the powers to watch carefully over the manner in which the promises of the Porte should be fulfilled, and reserving to them the right, in case their hopes were again disappointed, to consider in common as to the means best fitted to secure the well being of the Christian population and general peace. Separate declarations were made by the representatives of Great Britain, Russia, and Italy, which greatly modified the appearance of unanimity; and on April 16 Prince Gortchakoff informed Lord Derby that if the Porte's reply should prove unsatisfactory, the time for military action would have arrived. Three days later the Porte angrily rejected the protocol, on the same grounds as it had the proposals of the conference—that it was a disrespectful outside pressure for reforms which the Porte professed itself willing to initiate of its own motion, and involved a virtual abdication of sovereignty in its European provinces.—On April 24 the Russian emperor issued at Kisheneff, the headquarters of the army which had for six months been massed on the Roumanian frontier, a manifesto to his people declaring war, and 50,000 of his troops the same day crossed the Pruth into Roumania. At

the same time, in Asia, a Russian army of some 70,000 men, under the grand duke Michael and Gen. Loris-Melikoff, crossed the Turkish frontier in Transcaucasia, and advanced on Kars and Batum. The army which now proceeded to occupy the Roumanian bank of the Danube was commanded by the grand duke Nicholas, and was supposed to be 200,000 strong, but many of the battalions were incomplete in numbers. A convention was arranged with Roumania by which a free passage was granted the Russians, and two months were occupied in moving men and stores to the banks of the Danube. These operations might have been seriously obstructed by the Turks, had not their commanding general, Abdul-Kerim Pasha, been old and incapable, and no important action took place. On June 24 a Russian force crossed the Danube by bridges of boats at Braila and Galatz, and occupied Matchin. Three days afterward the main army crossed further up at Simnitsa, and occupied Sistova. A small body of cavalry pushed on and occupied Tirnova, the ancient capital of Bulgaria, and a civil government, composed chiefly of Bulgarians under a Russian commander, was established there. On July 16 Nicopolis was surrendered to Gen. Krüdener after a day's bombardment. Gen. Gurko with a flying column crossed the Balkans by a difficult pass pointed out to him by Bulgarians, and took the Shipka pass in reverse. Osman Pasha, who had started from Widin for the relief of Nicopolis, turned aside and occupied Plevna, beginning the construction of defences which in time became very formidable. About the same time Mehemet Ali (a German by birth) and Suleiman Pasha were recalled from Montenegro, which in the preceding months had almost been resubdued, and the former was appointed to succeed Abdul-Kerim, while Suleiman was given an independent command in Roumelia. On July 20 the Russians received their first check in Europe, Gen. Schilder-Schuldner's attack upon Plevna being repulsed with severe loss. Reinforcements were pushed forward, and even a Roumanian corps crossed the Danube; but Osman was strengthened also until he had a force of nearly 50,000 men, and when attacked on July 30 by Gen. Krüdener and Prince Shakhovski, he inflicted a severe defeat and a loss of upward of 7,000 men upon the Russians. At the same time Gen. Gurko, who had penetrated within 30 miles of Adrianople, was forced to fall back before Suleiman into the Shipka pass, where, after a desperate ten days' struggle, involving heavy losses on both sides, the Russians, under Gen. Radetzky, succeeded in maintaining themselves. On the Lom the cesarevitch was repulsed by Mehemet Ali, who obtained the entire left bank of that stream. The whole imperial guard was now sent forward from Russia, the mobilization of 188,000 men of the landwehr was ordered, and the entire Roumanian army crossed the Danube under Prince Charles. On Sept. 11 an-

other grand assault was made on Plevna in the presence of the emperor. On the left the younger Gen. Skobelev, at a terrible expense of life, captured three redoubts, which were retaken by the Turks the next day. On the right the hitherto despised Roumanians captured and held the Grivitza redoubt. But the general result of the attack was so disastrous to the Russians that they abandoned all hope of success by assault, and Gen. Todleben was summoned from Russia to undertake the reduction of Plevna by a regular siege. Lovatz, south of Plevna, had on Sept. 3 been captured by Gen. Skobelev; and while Suleiman was wasting his strength in new efforts to dislodge the Russians in the Shipka pass, and the Turks on the Lom were making weak demonstrations against the cesarevitch, Gen. Gurko with the imperial guards was capturing Dubnik, Telish, and Etropol, and cutting off Osman's south-western communications. In spite of 10,000 men sent out from Sophia by Shefket Pasha, the butcher of Bulgaria, who forced a passage through the Russian lines during the last of September, by the end of October the isolation of Plevna was complete. Driven by hunger, Osman made a sortie on Dec. 10, in the hope of breaking through the Russian lines and reaching Widin. Crossing the Vid, he was repulsed after a desperate fight, and attempted to reënter his works; but finding them occupied by the enemy, he surrendered his whole force of 30,000 men, including 10 pashas and 78 guns. Servia, which had been waiting to make sure that Russia was to be successful, now declared war against Turkey, and on Dec. 15 her troops crossed the frontier. They soon captured several towns, and the Timok corps effected a junction with the Russians. Prince Nicholas of Montenegro had improved the departure of the Turkish forces to capture Niksitch, Presieka, and Bilek in Herzegovina in September, and Spuz and Antivari in Albania at a later period. —Of the three armies that invaded Turkey in Asia in the spring of 1877, one captured Ardahan by assault; to another Bayazid was abandoned; while the centre invested Kars. The Turks at the same time landed forces in Russian territory, captured Sukhum Kaleh, and excited a revolt among the Circassians. The Russians in Bayazid were besieged by Faik Pasha, and only rescued by a gallant feat of arms performed by Gen. Tergukasoff. In June Mukhtar Pasha, who had been unsuccessful formerly in his Montenegrin campaign, but now had the general command of the Turks in Asia, inflicted severe defeats upon that portion of the Russian centre which had been pushed on to Delibaba and Zevin, and relieved Kars. In the middle of July Gen. Melikoff raised the siege of Kars, and almost the whole of Turkish Armenia was evacuated by the Russians. After receiving reënforcements, they advanced again against Mukhtar, who had been weakened by the loss of troops detached for service in Europe. In the beginning of October there were

several days of fighting in the neighborhood of Kars, ending in a great battle at the Aladjadagh on Oct. 15, and in the almost complete destruction of Mukhtar's army of 35,000 men, of whom about 10,000 were captured. The Deve-Boyun position before Erzerum was taken early the next month. Other Russian operations against the Armenian capital were unsuccessful, but ample compensation was found for this in the capture by assault of the famous stronghold of Kars, on Nov. 18, with 300 guns and 10,000 prisoners. The investment of Erzerum followed.—In Europe, after the fall of Plevna, Gen. Gurko turned the Turkish left flank in the Etropol Balkans, and on Jan. 3, 1878, he occupied Sophia, in whose streets a Christian army was seen for the first time since 1434. The Turkish Balkan army of 32,000 men and 93 guns, defeated at Shipka by Gen. Skobelev, and attacked on the other side by the Russian army issuing from the Shipka pass, surrendered on Jan. 9 to Gen. Radetzky. At the same time Nish surrendered to the Servians. Gurko advanced and occupied Philippopolis, routing and putting to flight Suleiman's army; and on Jan. 20 Radetzky's corps occupied Adrianople without firing a gun. The Turkish government at the beginning of the year had induced England to approach the emperor Alexander with a view to bringing about a truce, and an armistice was concluded between the combatants at Adrianople on Jan. 31. Skobelev, however, continued to advance until his troops were at Tchatalja, in sight of Constantinople. A British fleet thereupon passed the Dardanelles, and England and Russia were at the point of coming to blows. Negotiations proceeded between Turkey and Russia, and a treaty was signed on March 3 at San Stefano, on the sea of Marmora, 12 miles from Constantinople, to which the grand duke Nicholas's headquarters had been removed. It provided for the autonomy of Bulgaria, which province was to include the country between the Danube and the Balkans and the greater part of Thrace and Macedonia, thus stretching from the Black sea to the Archipelago, and was to be controlled for two years by a Russian commission, and to be occupied by 50,000 Russian troops; independence for Montenegro, and the cession to her of such territory as she had conquered; independence for Roumania and Servia, with the cession to the former of the Dobrudja, and to the latter of territory in Bosnia; an autonomous administration for Bosnia and Herzegovina with adequate guarantees, and similar reforms in the other Christian provinces; the cession to Russia of Roumanian Bessarabia, which had been taken from her by the treaty of Paris, and, in lieu of a war indemnity of about \$1,050,000,000, of Batum, Kars, Bayazid, Ardahan, and adjacent territory; absolute freedom of the straits to merchantmen, and prohibition of their passage by men-of-war; and the payment to Russia, for the indemnification of private losses, of about \$200,000 in bonds, the interest

to be guaranteed by the Bulgarian and Egyptian tributaries. Austria and England declared this treaty irreconcilable with their interests, and the former proposed the settlement of the matter by a European congress. England refused to attend unless Russia would engage to submit every clause of the San Stefano treaty, while the latter reserved a veto upon all matters which in her opinion did not fall within European jurisdiction. At this deadlock Lord Beaconsfield ordered a contingent of Indian troops to Malta, and was sustained by parliament when the subject came before that body. The difficulty was solved by a secret agreement between Russia and England, by which the latter agreed to yield to some of the Russian demands in Europe, on condition that no further advance should be made toward the British frontier in Asia. On June 3 Germany issued invitations to the signatories of the treaties of 1856 and 1871 to send to Berlin ambassadors to discuss the treaty of San Stefano. The sitting of the congress began on June 13, and on July 13 the treaty of Berlin was signed. The chief modifications which it effected upon the San Stefano treaty were as follows: Bosnia and Herzegovina were handed over to be occupied and administered by Austria; the territory ceded to Montenegro was cut down on the southeast to a narrow strip with a frontage on the sea of only about 7 miles, about 30 square miles at this point being ceded to Austria; Montenegro was forbidden to have a navy, and her acquired harbor of Antivari was forbidden all ships of war; the territory ceded to Serbia was largely reduced; the tributary principality of Bulgaria was established on the former basis of Serbia and Roumania, but its proportions were so cut down as to extend only from Sophia and Widin on the west to Varna and Silistria on the east, and to include no territory south of the Balkans; south of Bulgaria, and running in a long parallelogram from near the Little Kara-su to the Black sea, was erected the new province of Eastern Roumelia, under the direct political authority of the sultan, who might keep regular but not irregular troops there, but with a Christian governor and native militia; the rectification of the Greek frontier was recommended; the Russian army in European Turkey was to be removed in a year; Batum, though ceded to Russia, was to lose its fortifications; Bayazid was to be restored to Turkey, and the town and valley of Kotur to Persia; difference of religion was not to be an obstacle to political rights anywhere in the Turkish empire. Altogether Turkey lost 83,300 square miles of territory and 4,882,000 inhabitants. About the time of the conclusion of the treaty it was learned that England and Turkey had entered into a secret agreement by which the former engaged to defend her ally's Asiatic territory if ever attacked, and in return received control, though not absolute possession, of Cyprus. Under this treaty an Austrian army marched into Bosnia, but it was

only after a campaign of several months that the Mohammedan insurgents were reduced to submission, and the country pacified. A constituent assembly of Bulgaria at Tirnova in April, 1879, elected for its prince Alexander of Battenberg, a son of Prince Alexander of Hesse and a nephew of the empress of Russia. In May the sultan appointed Prince Alexander Vogorides (Aleko Pasha) governor general of Eastern Roumelia. The Albanians resisted the efforts to rectify the Montenegrin frontier on the south, and Mehemet Ali, who was sent from Constantinople to quiet them, lost his life in a riot. Disorder has continued in this quarter, encouraged, it is generally believed, by the Turkish authorities; and the Porte has also so far evaded coming to any agreement with Greece on the frontier question.—See "War Correspondence of the Daily News" (2 vols., London, 1878); "Armenia and the Campaign of 1877," by C. B. Norman (London, 1878); and "The Russian Army and its Campaigns in Turkey," by F. V. Greene, U. S. A. (New York, 1879).

RUTHERFORD, Lewis Morris, an American inventor, born in Morrisania, N. Y., Nov. 25, 1816. He graduated at Williams college in 1834, studied law, and entered into partnership with Hamilton Fish. He has devoted himself largely to astronomical photography, on which and kindred subjects he has published numerous papers. He has invented a dividing engine, a micrometer for measuring photographs taken with a telescope, and other apparatus for similar purposes.

RYLE, John Charles, an English author, born in Macclesfield in 1816. He was educated at Eton and Oxford, took orders, served as curate of Exbury in the New Forest, and became rector of St. Thomas's, Winchester, in 1843, rector of Helmingham, Suffolk, in 1844, and vicar of Stradbroke in 1861. In 1871 he was made honorary canon of Norwich cathedral. In 1880 he was chosen to be dean of Salisbury (which post he did not take), and the same year was appointed first bishop of the newly established see of Liverpool. Bishop Ryle's publications include "Expository Thoughts on the Gospels" (6 vols.), "Hymns for the Church on Earth," "Coming Events and Present Duties," "The Bishops and Clergy of other Days," "The Christian Leaders of the Last Century," and a large number of "Tracts for the People," which have been translated into most of the continental languages, and have circulated largely in the United States and Canada.

SAINT GOTHARD TUNNEL. This new passage through the Alps was opened for traffic in May, 1882. It presents the straightest and shortest route between central Europe and Italy, and makes Genoa a port for German commerce in the Mediterranean. It was projected as early as 1848, but was not really attempted till after

the consolidation of Italy and the formation of the North German Bund. Great difficulty was experienced in reconciling the conflicting interests of the Swiss cantons, and at one time their dispute seemed likely to result in civil war. The main tunnel is 14,944 metres in length (about $9\frac{1}{4}$ miles), and is the longest in the world. Besides this, there are, in the approaches, 53 shorter tunnels, making a total length of 40,718 metres ($25\frac{1}{4}$ miles). The highest point is 3,693 feet above sea-level; that of the Mont Cenis is 4,043. The St. Gothard has little ventilation, and the temperature in its interior is 88° Fahr. The cost was about \$44,000,000.

SALICYLATE OF SODIUM, a medicine which is prepared by adding salicylic acid to a 10 per cent. solution of caustic soda as long as it is dissolved, filtering, and evaporating to dryness; or 10 parts of pure crystallized carbonate of sodium may be added to 10 parts of salicylic acid, previously mixed with sufficient water to make a thin paste. After the evolution of carbonic acid has ceased, the solution is perfectly neutralized with caustic soda, and evaporated to dryness. Salicylate of sodium is a white powder, having at first a sweet and afterward an acrid taste. It is soluble in about its own weight of cold water. Like salicylic acid, it exerts a powerful influence over acute rheumatism. In the majority of cases, the excruciating pain is very promptly relieved, while the swelling rapidly diminishes. Being much more soluble, it is generally preferred to salicylic acid. It may be given in doses of 20 grains every two hours until the pain abates, or until six doses have been taken; then the dose should be smaller, or be taken at longer intervals. It may be administered in water alone, or in aromatic water, or sirup. When used too long or in too large doses, it may produce roaring of the ears, dimness of vision, delirium, &c.

SANT, James, a British artist, born in Croydon, April 23, 1820. He was a pupil of Varley, and began his career as a portrait painter. His pictures include, besides numerous portraits of celebrated people, "Samuel," "Children of the Wood," "Little Red Ridinghood," "The First Sense of Sorrow," "Turn Again, Whittington," "Light in Dark Places," "Mentonese Children," "The Schoolmaster's Daughter," "The Early Post," "Gleanings," "Little Zara," "The Light of the Cross," "Mother's Hope," "She never Told her Love," "Saxon Women," "The Boy Shakespeare," "The Walk to Emmaus," and "The Miller's Daughter." He became an academician in 1870, and in 1871 principal painter in ordinary to the queen.

SANTLEY, Charles, an English singer, born in Liverpool about 1840. He studied in England and in Italy, and first appeared in opera at Covent Garden in 1860. He took rank from the first as one of the most effective barytones on the stage, and has sung in most of the capitals of Europe, confining himself mainly to Italian opera. In the United States he appeared in 1878 in concerts and in operas.

SAYCE, Archibald Henry, an English philologist, born near Bristol, Sept. 25, 1846. He was educated at Oxford, where he was for some time a tutor, took orders in 1870, and in 1876 became deputy professor of comparative philology and professor of Celtic. He is also a public examiner in the school of theology, and a member of the Old Testament revision company. He has published "An Assyrian Grammar for Comparative Purposes" (1872); "The Principles of Comparative Philology" (1874); "The Astronomy and Astrology of the Babylonians" (1874); "Babylonian Literature" (1877); "Introduction to the Science of Language" (2 vols. 8vo, 1880); and numerous lectures and papers in periodicals. He has also edited George Smith's "History of Babylonia" (1877).

SCHARF, George, an English artist, born in London, Dec. 16, 1820. His father, of the same name, was a Bavarian artist, who emigrated to London and died there in 1860. The son was educated at London university school, and studied art under his father and at the royal academy. He travelled in Italy in 1840, and in 1843 in Asia Minor as draughtsman of a government expedition. He has published "Scenic Effects," a series of etchings illustrating the Shakespearian and classic revivals by Macready, and has illustrated numerous standard books. He has also lectured and written extensively on art subjects, being an authority on historical portraits, among which he has made some notable discoveries, and has prepared elaborate catalogues of several famous collections. There is a large collection of his drawings, Lycian views, and outlines of sculpture, in the British museum.

SCHIRMER, Johann Wilhelm, a German landscape painter, born at Jülich, Sept. 5, 1807, died Sept. 11, 1863. He was a pupil of Schadow. He was the founder of the Düsseldorf landscape school, and the creator of what is called historical landscape. His best works are "Scenes from the Odyssey" and "Biblical Landscapes."

SCHUYLER, Eugene, an American author, born in Ithaca, N. Y., in 1840. He graduated at Yale college in 1859, and at Columbia college law school in 1863. He was appointed consul at Moscow in 1866 and secretary of legation at St. Petersburg in 1869, became a proficient in the Russian language, and made in 1873 a journey in Russian Turkistan, Khokan, and Bokhara, embodying the results in a work entitled "Turkistan" (2 vols., 1876). In 1875 he was appointed consul general and secretary of legation at Constantinople, and in 1876 made a journey through Bulgaria, visiting the scenes of the Turkish atrocities, and making an extended report of his observations to his government. In 1878 he was appointed consul at Birmingham, in 1879 consul at Rome, and in 1880 representative of the United States in Roumania. In 1878 he published "The Cossacks, a Tale of the Caucasus in 1852," translated from the Russian of Count L. Tolstoi; and in 1879 he be-

gan the publication in "Scribner's Monthly" of an extended life of Peter the Great. In 1877 he was elected a corresponding member of the royal geographical society of London, a member of the royal Asiatic society of London, and of the *société asiatique* of Paris.

SCOTT, Julian, an American artist, born in Vermont about 1840. He served with a Vermont regiment in the civil war, and became noted for his charcoal sketches of army life. After the war he opened a studio in New York. His pictures include "Gen. O. B. Willcox in Libby Prison," "The Rear Guard at White Oak Swamp," "Near the Outposts," "Cavalry Charge near Ashby's Gap," "On Board the Hartford," "Reserves Awaiting Orders," "A Camp Raid," "The Duel of Burr and Hamilton," "The Capture of André," and in water-colors "New England Turkey-Shoot," "Changing Guard, 1776," and "On Guard, 1861."

SCOTT-SIDDONS, Mary Frances, an English actress, born in 1848. She is a daughter of Capt. William Siddons, who was a grandson of the actress Mrs. Sarah Siddons. She married Lieut. Scott, a British naval officer, in 1864, and two years later made her first appearance on the stage in Edinburgh, as Juliet. In 1867 she gave readings from Shakespeare in London, and appeared at the Haymarket as Rosalind. In 1868 she gave readings in New York, and entered upon an engagement at the Fifth Avenue theatre. Since that time she has performed in most of the cities of the United States, Australia, and England, appearing mainly in Shakespearean characters, but also as Pauline in "The Lady of Lyons," and as Coralie in "Ordeal by Touch," written for her by Richard Lee.

SEELYE, Julius Hawtrej, an American educator, born in Bethel, Conn., in 1824. His early education was obtained at the school and academy in his native place. He graduated at Amherst college in 1849, and studied theology at Auburn, N. Y., 1849-'52, and at Halle, Germany, 1852-'53. He became pastor of the first Reformed Dutch church in Schenectady, N. Y., in 1853, and remained there till 1858, when he was elected professor of mental and moral philosophy at Amherst college, which chair he still holds (1883). In 1872 he visited India. He became president of Amherst college in 1876. Dr. Seelye has published a translation of Schwegler's "History of Philosophy" (12mo, New York, 1856); "Lectures to Educated Hindus" (Bombay, 1873; republished by the Congregational publishing society, Boston, 1873, under the title, "The Way, the Truth, the Life;," also translated into Hindustani, Japanese, and German); "Christian Missions" (12mo, New York, 1875), and a revision of Hickok's "Moral Science" (12mo, Boston, 1880). President Seelye has also contributed to various reviews, and published sermons and addresses. He was elected to congress in 1874 and 1876, and, though a republican, opposed the electoral commission and the declaration that Mr. Hayes had been elected president.

SERPA-PINTO, Alexander Albert da Rocha, a Portuguese explorer, born in Tendaes, April 20, 1846. He entered the military school in 1858, and received a lieutenant's commission in 1864. In 1869 he served with distinction in the military expedition against the rebellious chief Bonga in the Zambesi region, on which occasion he followed up that river to the Victoria falls. After the close of the campaign he undertook a hunting expedition to the Shiré and Lake Nyassa, passing some time among the Comore and Seychelle, and returning to Europe by way of Goa. His unusual scientific attainments, familiarity with African life, and thorough knowledge of the native idioms, pointed him out as a desirable member of the exploratory expedition sent into the interior of Africa by the Portuguese government. Starting from the Benguela coast in November, 1877, in company with Brito Capello and Robert Ivens, and reaching Bihé in March, 1878, he separated from his companions and made his way across the African continent by a southeasterly route, arriving at Durban April 14, 1879. Serpa-Pinto explored the head waters of the Cubango, which rises in an elevated plateau in the immediate vicinity of the sources of the Cuanza, which flows into the Atlantic, and of the Cuando or Tchobe, the principal affluent of the Zambesi. He reported the discovery in this region of an African race living in the lowest savagery, with tufted hair like the Hottentots, but of white complexion. He ascertained with tolerable certainty that the Cubango, whose waters (as far as they escape evaporation and absorption) enter Lake Ngami, has no connection with the Zambesi, but that the overflow from that lake, when any occurs, passes into an immense salt pan called Macacariari.

SEVEN WONDERS OF THE WORLD, the title of a book (*Περὶ τῶν ἑπτὰ θαυμάτων*) attributed doubtfully to Philo of Byzantium, who lived in the second century before Christ and wrote a treatise on mechanics. This title has passed into a proverbial expression, and much confusion has arisen with regard to its exact meaning. The only known manuscript of the work referred to was carried to Paris from the Vatican library during the reign of Napoleon I. The last chapter is lost, and the preceding one is badly mutilated. It was first edited by Al-latius, with a Latin translation (Rome, 1640). The best edition is Orelli's (Leipsic, 1816). The seven wonders enumerated and described are: 1. The hanging gardens and walls of Babylon. 2. The pyramids of Egypt. 3. The statue of Jupiter, at Athens, by Phidias. 4. The colossus at Rhodes. 5. The pharos of Alexandria. 6. The temple of Diana at Ephesus. 7. The tomb of Mausolus at Halicarnassus. The last chapter of the manuscript treated of the Mausoleum, and the mutilated one of the temple of Diana. In some enumerations, the palace of Cyrus, which was said to be cemented with gold, is substituted for the pharos of Alexan-

dria.—The preceding are sometimes called "the seven wonders of antiquity," as there is another list, known as "the seven wonders of the middle ages." These are: 1. The Coliseum at Rome. 2. The catacombs of Alexandria. 3. The great wall of China. 4. The Druidical temple at Stonehenge, England. 5. The leaning tower of Pisa. 6. The porcelain tower of Nankin. 7. The mosque of St. Sophia at Constantinople.

SHAIRP, John Campbell, a Scottish author, born in Linlithgowshire about 1835. He was educated at Glasgow and Oxford, was an assistant master at Rugby, and in 1868 became principal of the united college of St. Salvador and St. Leonards, at St. Andrews. He has published "Kilmahoe, a Highland Pastoral, with other Poems" (1864); "Studies in Poetry and Philosophy" (1868); "Lectures on Culture and Religion" (1870); "The Poetic Interpretation of Nature" (1877); and a "Life of Burns" (1880).

SHATTUCK, Aaron D., an American painter, born in New Hampshire in 1832. He studied art in Boston, and was for a time a portrait painter, but finally settled in New York. He was elected to the national academy in 1861. His works include "Glimpses of Lake Champlain," "Autumnal Views of Androscoggin Scenery," "Morning Light," "The New Eng-

land Farm," "White Hills in October," "The Old Homestead," "Haying Time," "The Road to Simsbury, Conn.," "Autumn near Stockbridge, Mass.," "Cranberry Pastures," and numerous cattle pieces.

SHAW, Henry W., an American humorist, born in Lanesborough, Mass., in 1818. He removed to the west at an early age, and became a farmer. Afterward for 25 years he was an auctioneer, settling in Poughkeepsie, N. Y. His first production in print appeared in 1863, bearing the pen name of "Josh Billings," by which he has since been known. His writings consist largely of quaint maxims in phonetic spelling, produced in small instalments for a New York weekly paper. He has lectured extensively, and has published four volumes of his sketches, besides an annual "Almanax." A life of him, by Francis S. Smith, was published in New York in 1886.

SHIRLAW, Walter, an American artist, born in Paisley, Scotland, in 1837. His parents emigrated to Chicago when he was a child. He studied in Munich, and settled in New York, where he is now a professor in the art students' league. His pictures include "Toning of the Bell," "Sheep Shearing in the Bavarian Highlands," "Feeding the Poultry," "The Bather," "Good Morning," and "The Young Patrician."
